Where the network is unstable and members frequently lose and regain connection to each other in different combinations, it is theoretically possible for a group to end up marking all its members for expulsion, after which the group would cease to exist and have to be set up again. To counter this possibility, the Group Replication Group Communication System (GCS) tracks the group members that have been marked for expulsion, and treats them as if they were in the group of suspected members when deciding if there is a majority. This ensures at least one member remains in the group and the group can continue to exist. When an expelled member has actually been removed from the group, GCS removes its record of having marked the member for expulsion, so that the member can rejoin the group if it is able to.

For information on the Group Replication system variables that you can configure to specify the responses of working group members to failure situations, and the actions taken by group members that are suspected of having failed, see Section 20.7.7, “Responses to Failure Detection and Network Partitioning”.

### 20.1.4.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers \( n \) needed to tolerate \( f \) failures is then \( n = 2 \times f + 1 \).

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails involuntarily, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

<table>
<thead>
<tr>
<th>Group Size</th>
<th>Majority</th>
<th>Instant Failures Tolerated</th>
</tr>
</thead>

</table>

### 20.1.4.4 Observability

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through Performance Schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus synchronize on transactions and metadata makes it simpler to inspect the state of the group. For example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see Section 20.4, “Monitoring Group Replication”.

### 20.1.5 Group Replication Plugin Architecture
MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.

**Figure 20.6 Group Replication Plugin Block Diagram**

The MySQL Group Replication plugin includes a set of APIs for capture, apply, and lifecycle, which control how the plugin interacts with MySQL Server. There are interfaces to make information flow from the server to the plugin and vice versa. These interfaces isolate the MySQL Server core from the Group Replication plugin, and are mostly hooks placed in the transaction execution pipeline. In one direction, from server to the plugin, there are notifications for events such as the server starting, the server recovering, the server being ready to accept connections, and the server being about to commit a transaction. In the other direction, the plugin instructs the server to perform actions such as committing or aborting ongoing transactions, or queuing transactions in the relay log.

The next layer of the Group Replication plugin architecture is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context.
related to transactions that are executing. The applier component is responsible for executing remote transactions on the database. The recovery component manages distributed recovery, and is responsible for getting a server that is joining the group up to date by selecting the donor, managing the catch up procedure and reacting to donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, and receives and propagates transactions to the group. The final two layers of the Group Replication plugin architecture are the Group Communication System (GCS) API, and an implementation of a Paxos-based group communication engine (XCom). The GCS API is a high level API that abstracts the properties required to build a replicated state machine (see Section 20.1, “Group Replication Background”). It therefore decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The group communication engine handles communications with the members of the replication group.

20.2 Getting Started

MySQL Group Replication is provided as a plugin for the MySQL server; each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three members.

Tip

To deploy multiple instances of MySQL, you can use InnoDB Cluster which enables you to easily administer a group of MySQL server instances in MySQL Shell. InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with MySQL Router, which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use InnoDB ReplicaSet. Installation instructions for MySQL Shell can be found here.

20.2.1 Deploying Group Replication in Single-Primary Mode

Each of the MySQL server instances in a group can run on an independent physical host machine, which is the recommended way to deploy Group Replication. This section explains how to create a replication group with three MySQL Server instances, each running on a different host machine. See Section 20.2.2, "Deploying Group Replication Locally" for information about deploying multiple MySQL server instances running Group Replication on the same host machine, for example for testing purposes.
This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

### 20.2.1.1 Deploying Instances for Group Replication

The first step is to deploy at least three instances of MySQL Server, this procedure demonstrates using multiple hosts for the instances, named s1, s2, and s3. It is assumed that MySQL Server is installed on each host (see Chapter 2, *Installing MySQL*). The Group Replication plugin is provided with MySQL Server 8.4; no additional software is required, although the plugin must be installed in the running MySQL server. See Section 20.2.1.1, “Deploying Instances for Group Replication”; for additional information, see Section 7.6, “MySQL Server Plugins”.

In this example, three instances are used for the group, which is the minimum number of instances to create a group. Adding more instances increases the fault tolerance of the group. For example if the group consists of three members, in event of failure of one instance the group can continue. But in the event of another failure the group can no longer continue processing write transactions. By adding more instances, the number of servers which can fail while the group continues to process transactions also increases. The maximum number of instances which can be used in a group is nine. For more information see Section 20.1.4.2, “Failure Detection”.

### 20.2.1.2 Configuring an Instance for Group Replication
Deploying Group Replication in Single-Primary Mode

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see Section 20.3, “Requirements and Limitations”.

- Storage Engines
- Replication Framework
- Group Replication Settings

Storage Engines

For Group Replication, data must be stored in the InnoDB transactional storage engine (for details of why, see Section 20.3.1, “Group Replication Requirements”). The use of other storage engines, including the temporary MEMORY storage engine, might cause errors in Group Replication. Set the disabled_storage_engines system variable as follows to prevent their use:

```
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"
```

Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```
server_id=1
gtid_mode=ON
enforce_gtid_consistency=ON
```

These settings configure the server to use the unique identifier number 1, to enable Section 19.1.3, “Replication with Global Transaction Identifiers”, and to allow execution of only statements that can be safely logged using a GTID.

This setting disables checksums for events written to the binary log, which default to being enabled. Group Replication in MySQL 8.4 supports the presence of checksums in the binary log and can use them to verify the integrity of events on some channels, so you can use the default setting. For more details, see Section 20.3.2, “Group Replication Limitations”.

See also Section 20.3.1, “Group Replication Requirements”.

Group Replication Settings

At this point the option file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```
plugin_load_add='group_replication.so'
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s1:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group=off
```

- plugin-load-add adds the Group Replication plugin to the list of plugins which the server loads at startup. This is preferable in a production deployment to installing the plugin manually.

- Configuring group_replication_group_name tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa". The value of group_replication_group_name must be a valid UUID. You can use SELECT UUID() to generate one. This UUID forms part of the GTIDs that are used when transactions received by group members from clients, and view change events that are generated internally by the group members, are written to the binary log.

- Configuring the group_replication_start_on_boot variable to off instructs the plugin to not start operations automatically when the server starts. This is important when setting up Group Replication as it ensures you can configure the server before manually starting the plugin. Once the
Deploying Group Replication in Single-Primary Mode

- Configuring `group_replication_start_on_boot` sets the network address and port which the member uses for internal communication with other members in the group. Group Replication uses this address for internal member-to-member connections involving remote instances of the group communication engine (XCom, a Paxos variant).

  • Configuring `group_replication_local_address` sets the network address and port which the member uses for internal communication with other members in the group. Group Replication uses this address for internal member-to-member connections involving remote instances of the group communication engine (XCom, a Paxos variant).

    ! Important

    The group replication local address must be different to the host name and port used for SQL client connections, which are defined by MySQL Server's `hostname` and `port` system variables. It must not be used for client applications. It must be only be used for internal communication between the members of the group while running Group Replication.

    The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. IPv6 addresses (or host names that resolve to them) can be used as well as IPv4 addresses; a group can contain a mix of members using IPv6 and members using IPv4. For more information on Group Replication support for IPv6 networks and on mixed IPv4 and IPv6 groups, see Section 20.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.

    The recommended port for `group_replication_local_address` is 33061. This is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, as demonstrated in this tutorial. Alternatively you can use the same host name or IP address for all members as long as the ports are all different, for example as shown in Section 20.2.2, “Deploying Group Replication Locally”.

    The connection that an existing member offers to a joining member for Group Replication's distributed recovery process is not the network address configured by `group_replication_local_address`. Group members offer their standard SQL client connection to joining members for distributed recovery, as specified by MySQL Server's `hostname` and `port`; they may (also) advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members. For more details, see Section 20.5.4.1, “Connections for Distributed Recovery”.

    ! Important

    Distributed recovery can fail if a joining member cannot correctly identify the other members using the host name as defined by MySQL Server's `hostname` system variable. It is recommended that operating systems running MySQL have a properly configured unique host name, either using DNS or local settings. The host name that the server is using for SQL client connections can be verified in the `Member_host` column of the Performance Schema table `replication_group_members`. If multiple group members externalize a default host name set by the operating system, there is a chance of the joining member not resolving it to the correct member address and not being able to connect for distributed recovery. In this situation you can use MySQL Server's `report_host` system variable to configure a unique host name to be externalized by each of the servers.

• Configuring `group_replication_group_seeds` sets the hostname and port of the group members which are used by the new member to establish its connection to the group. These members are called the seed members. Once the connection is established, the group membership
Deploying Group Replication in Single-Primary Mode

Information is listed in the Performance Schema table `replication_group_members`. Usually, the `group_replication_group_seeds` list contains the hostname:port of each of the group member's `group_replication_local_address`, but this is not obligatory and a subset of the group members can be chosen as seeds.

**Important**

The hostname:port listed in `group_replication_group_seeds` is the seed member's internal network address, configured by `group_replication_local_address` and not the hostname:port used for SQL client connections, which is shown for example in the Performance Schema table `replication_group_members`.

The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. In other words, any existing data which is on the server bootstrapping the group is what is used as the data for the next joining member. The second server joining asks the one and only member in the group to join, any missing data on the second server is replicated from the donor data on the bootstrapping member, and then the group expands. The third server joining can ask any of these two to join, data is synchronized to the new member, and then the group expands again. Subsequent servers repeat this procedure when joining.

**Warning**

When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they might not yet be in the group when contacted.

It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

Creating a group and joining multiple members at the same time is not supported. It might work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

A joining member must communicate with a seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the `group_replication_group_seeds` option. For the purpose of IP address permissions for Group Replication, the allowlist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and permitted in addition to the joining member's `group_replication_local_address` if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information, see Section 20.6.4, “Group Replication IP Address Permissions”.

- Configuring `group_replication_bootstrap_group` instructs the plugin whether to bootstrap the group or not. In this case, even though s1 is the first member of the group we set this variable to off in the option file. Instead we configure `group_replication_bootstrap_group` when the instance is running, to ensure that only one member actually bootstraps the group.

**Important**

The `group_replication_bootstrap_group` variable must only be enabled on one server instance belonging to a group at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an artificial split brain scenario, in which two distinct groups with the same name.
Deploying Group Replication in Single-Primary Mode

exist. Always set `group_replication_bootstrap_group=off` after the first server instance comes online.

The system variables described in this tutorial are the required configuration settings to start a new member, but further system variables are also available to configure group members. These are listed in Section 20.9, “Group Replication Variables”.

**Important**

A number of system variables, some specific to Group Replication and others not, are group-wide configuration settings that must have the same value on all group members. If the group members have a value set for one of these system variables, and a joining member has a different value set for it, the joining member cannot join the group and an error message is returned. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group. These system variables are all identified in Section 20.9, “Group Replication Variables”.

**20.2.1.3 User Credentials For Distributed Recovery**

Group Replication uses a distributed recovery process to synchronize group members when joining them to the group. Distributed recovery involves transferring transactions from a donor's binary log to a joining member using a replication channel named `group_replication_recovery`. You must therefore set up a replication user with the correct permissions so that Group Replication can establish direct member-to-member replication channels. If group members have been set up to support the use of a remote cloning operation as part of distributed recovery, this replication user is also used as the clone user on the donor, and requires the correct permissions for this role too. For a complete description of distributed recovery, see Section 20.5.4, “Distributed Recovery”.

The same replication user must be used for distributed recovery on every group member. The process of creating the replication user for distributed recovery can be captured in the binary log, and then you can rely on distributed recovery to replicate the statements used to create the user. Alternatively, you can disable binary logging before creating the replication user, and then create the user manually on each member, for example if you want to avoid the changes being propagated to other server instances. If you do this, ensure you re-enable binary logging once you have configured the user.

**Important**

If distributed recovery connections for your group use SSL, the replication user must be created on each server before the joining member connects to the donor. For instructions to set up SSL for distributed recovery connections and create a replication user that requires SSL, see Section 20.6.3, “Securing Distributed Recovery Connections”.

**Important**

By default, users created in MySQL 8 use Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”. If the replication user for distributed recovery uses the caching SHA-2 authentication plugin, and you are not using SSL for distributed recovery connections, RSA key-pairs are used for password exchange. You can either copy the public key of the replication user to the joining member, or configure the donors to provide the public key when requested. For instructions to do this, see Section 20.6.3.1, “Secure User Credentials for Distributed Recovery”.

To create the replication user for distributed recovery, follow these steps:

1. Start the MySQL server instance, then connect a client to it.
2. If you want to disable binary logging in order to create the replication user separately on each instance, do so by issuing the following statement:
Deploying Group Replication in Single-Primary Mode

mysql> SET SQL_LOG_BIN=0;

3. Create a MySQL user with the following privileges:

- **REPLICATION SLAVE**, which is required for making a distributed recovery connection to a donor to retrieve data.
- **CONNECTION_ADMIN**, which ensures that Group Replication connections are not terminated if one of the servers involved is placed in offline mode.
- **BACKUP_ADMIN**, if the servers in the replication group are set up to support cloning (see Section 20.5.4.2, “Cloning for Distributed Recovery”). This privilege is required for a member to act as the donor in a cloning operation for distributed recovery.
- **GROUP_REPLICATION_STREAM**, if the MySQL communication stack is in use for the replication group (see Section 20.6.1, “Communication Stack for Connection Security Management”). This privilege is required for the user account to be able to establish and maintain connections for Group Replication using the MySQL communication stack.

In this example the user `rpl_user` with the password `password` is shown. When configuring your servers use a suitable user name and password:

```sql
mysql> CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
mysql> GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%';
mysql> GRANT BACKUP_ADMIN ON *.* TO rpl_user@'%';
mysql> GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%';
mysql> FLUSH PRIVILEGES;
```

4. If you disabled binary logging, enable it again as soon as you have created the user, by issuing the following statement:

```sql
mysql> SET SQL_LOG_BIN=1;
```

5. When you have created the replication user, you must supply the user credentials to the server for use with distributed recovery. You can do this by setting the user credentials as the credentials for the `group_replication_recovery` channel, using a CHANGE REPLICATION SOURCE TO statement. Alternatively, you can specify the user credentials for distributed recovery in a START GROUP_REPLICATION statement.

- User credentials set using CHANGE REPLICATION SOURCE TO are stored in plain text in the replication metadata repositories on the server. They are applied whenever Group Replication is started, including automatic starts if the `group_replication_start_on_boot` system variable is set to ON.
- User credentials specified on START GROUP_REPLICATION are saved in memory only, and are removed by a STOP GROUP_REPLICATION statement or server shutdown. You must issue a START GROUP_REPLICATION statement to provide the credentials again, so you cannot start Group Replication automatically with these credentials. This method of specifying the user credentials helps to secure the Group Replication servers against unauthorized access.

For more information on the security implications of each method of providing the user credentials, see Providing Replication User Credentials Securely. If you choose to provide the user credentials using a CHANGE REPLICATION SOURCE TO statement, issue the following statement on the server instance now, replacing `rpl_user` and `password` with the values used when creating the user:

```sql
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user', SOURCE_PASSWORD='password' FOR CHANNEL 'group_replication_recovery';
```

20.2.1.4 Launching Group Replication
It is first necessary to ensure that the Group Replication plugin is installed on server s1. If you used `plugin_load_add='group_replication.so'` in the option file then the Group Replication plugin is already installed, and you can proceed to the next step. Otherwise, you must install the plugin manually; to do this, connect to the server using the `mysql` client, and issue the SQL statement shown here:

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
+----------------------------+----------+--------------------+----------------------+-------------+
| Name                       | Status   | Type               | Library              | License     |
+----------------------------+----------+--------------------+----------------------+-------------+
| binlog                     | ACTIVE   | STORAGE ENGINE     | NULL                 | PROPRIETARY |
| (…)                        |          |                    |                      |             |
| group_replication          | ACTIVE   | GROUP REPLICATION  | group_replication.so | PROPRIETARY |
+----------------------------+----------+--------------------+----------------------+-------------+
```

### 20.2.1.5 Bootstrapping the Group

The process of starting a group for the first time is called bootstrapping. You use the `group_replication_bootstrap_group` system variable to bootstrap a group. The bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the `group_replication_bootstrap_group` option was not stored in the instance’s option file. If it is saved in the option file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`. Therefore to safely bootstrap the group, connect to s1 and issue the following statements:

```
mysql> SET GLOBAL group_replication_bootstrap_group=ON;
mysql> START GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
```

Or if you are providing user credentials for distributed recovery on the `START GROUP_REPLICATION` statement, issue the following statements:

```
mysql> SET GLOBAL group_replication_bootstrap_group=ON;
mysql> START GROUP_REPLICATION USER='rpl_user', PASSWORD='password';
mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;

+---------------------------+--------------------------------------+-------------+-------------+---------------+-------------+----------------+----------------------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE  | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK |
|----------------------------|--------------------------------------|-------------|-------------|---------------|-------------|----------------|----------------------------+
| group_replication_applier | ce9be252-2b71-11e6-b8f4-00212844f856 | s1          | 3306        | ONLINE        |             |                | XCom                       |
+---------------------------+--------------------------------------+-------------+-------------+---------------+-------------+----------------+----------------------------+
1 row in set (0.0108 sec)
```

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `s1` listening for client connections on port `3306`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
```
Deploying Group Replication in Single-Primary Mode

Check the content of table `t1` and the binary log.

```sql
mysql> SELECT * FROM t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 | Luis |
+----+
```

```sql
mysql> SHOW BINLOG EVENTS;
```

As seen above, the database and the table objects were created and their corresponding DDL statements were written to the binary log. Also, the data was inserted into the table and written to the binary log, so it can be used for distributed recovery by state transfer from a donor’s binary log.

### 20.2.1.6 Adding Instances to the Group

At this point, the group has one member in it, server s1, which has some data in it. It is now time to expand the group by adding the other two servers configured previously.

#### Adding a Second Instance

In order to add a second instance, server s2, first create the configuration file for it. The configuration is similar to the one used for server s1, except for things such as the `server_id`. These different lines are highlighted in the listing below.

```conf
[mysqld]
#
# Disable other storage engines
# disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"
#
# Replication configuration parameters
# server_id=2
gtid_mode=ON
enforce_gtid_consistency=ON
#
# Group Replication configuration
# plugin_load_add='group_replication.so'
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s2:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
```
Deploying Group Replication in Single-Primary Mode

group_replication_bootstrap_group= off

Similar to the procedure for server s1, with the option file in place you launch the server. Then configure the distributed recovery credentials as follows. The commands are the same as used when setting up server s1 as the user is shared within the group. This member needs to have the same replication user configured in Section 20.2.1.3, “User Credentials For Distributed Recovery”. If you are relying on distributed recovery to configure the user on all members, when s2 connects to the seed s1 the replication user is replicated or cloned to s1. If you did not have binary logging enabled when you configured the user credentials on s1, and a remote cloning operation is not used for state transfer, you must create the replication user on s2. In this case, connect to s2 and issue:

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%';
GRANT BACKUP_ADMIN ON *.* TO rpl_user@'%';
GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
```

If you are providing user credentials using a CHANGE REPLICATION SOURCE TO, issue the following statement after that:

```
CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user', SOURCE_PASSWORD='password' 
FOR CHANNEL 'group_replication_recovery';
```

Tip

If you are using the caching SHA-2 authentication plugin (the default), see Replication User With The Caching SHA-2 Authentication Plugin.

If necessary, install the Group Replication plugin, see Section 20.2.1.4, “Launching Group Replication”.

Start Group Replication and s2 starts the process of joining the group.

```
mysql> START GROUP_REPLICATION;
```

Or if you are providing user credentials for distributed recovery on the START GROUP_REPLICATION statement:

```
mysql> START GROUP_REPLICATION USER='rpl_user', PASSWORD='password';
```

Unlike the previous steps that were the same as those executed on s1, here there is a difference in that you do not need to bootstrap the group because the group already exists. In other words on s2 group_replication_bootstrap_group is set to OFF, and you do not issue SET GLOBAL group_replication_bootstrap_group=ON; before starting Group Replication, because the group has already been created and bootstrapped by server s1. At this point server s2 only needs to be added to the already existing group.

Tip

When Group Replication starts successfully and the server joins the group it checks the super_read_only variable. By setting super_read_only to ON in the member’s configuration file, you can ensure that servers which fail when starting Group Replication for any reason do not accept transactions. If the server should join the group as a read-write instance, for example as the primary in a single-primary group or as a member of a multi-primary group, when the super_read_only variable is set to ON then it is set to OFF upon joining the group.

Checking the performance_schema.replication_group_members table again shows that there are now two ONLINE servers in the group.
Adding Additional Instances

1. Create the configuration file.

Verifying the synchronization between server s1 and s2:

When s2 attempted to join the group, Section 20.5.4, “Distributed Recovery” ensured that s2 applied the same transactions which s1 had applied. Once this process completed, s2 could join the group as a member, and at this point it is marked as ONLINE. In other words, it must have already caught up with server s1 automatically. Once s2 is ONLINE, it then begins to process transactions with the group. Verify that s2 has indeed synchronized with server s1 as follows.

Adding Additional Instances

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

1. Create the configuration file.
# Disable other storage engines
#
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"
#
# Replication configuration parameters
#
server_id=3
gtid_mode=ON
enforce_gtid_consistency=ON
#
# Group Replication configuration
#
plugin_load_add='group_replication.so'
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s3:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group= off

2. Start the server and connect to it. Create the replication user for distributed recovery.

```sql
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'';
GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'';
GRANT BACKUP_ADMIN ON *.* TO rpl_user@'';
GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
```

If you are providing user credentials using a `CHANGE REPLICATION SOURCE TO` statement, issue the following statement after that:

```sql
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user',
    -> SOURCE_PASSWORD='password'
    -> FOR CHANNEL 'group_replication_recovery';
```

3. Install the Group Replication plugin if necessary.

```sql
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

4. Start Group Replication.

```sql
mysql> START GROUP_REPLICATION;
```

Or, if you are providing user credentials for distributed recovery in the `START GROUP_REPLICATION` statement:

```sql
mysql> START GROUP_REPLICATION USER='rpl_user', PASSWORD='password';
```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the `performance_schema.replication_group_members` table again confirms this is the case.

```sql
mysql> SELECT * FROM performance_schema.replication_group_members;
```

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has caught up:

```sql
mysql> SHOW DATABASES LIKE 'test';
```
## 20.2.2 Deploying Group Replication Locally

The most common way to deploy Group Replication is using multiple server instances, to provide high
availability. It is also possible to deploy Group Replication locally, for example for testing purposes.
This section explains how you can deploy Group Replication locally.

### Important

Group Replication is usually deployed on multiple hosts because this ensures that high-availability is provided. The instructions in this section are not suitable for production deployments because all MySQL server instances are running on the same single host. In the event of failure of this host, the whole group fails. Therefore this information should be used for testing purposes and it should not be used in a production environments.

This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and that you need to configure each instance independently. This procedure assumes that MySQL Server was downloaded and unpacked - into the directory named `mysql-8.4`. Each MySQL server instance requires a specific data directory. Create a directory named `data`, then in that directory create a subdirectory for each server instance, for example `s1`, `s2` and `s3`, and initialize each one.

```
$ mysql-8.4/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.4 --datadir=$PWD/data/s1
$ mysql-8.4/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.4 --datadir=$PWD/data/s2
$ mysql-8.4/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.4 --datadir=$PWD/data/s3
```
Inside `data/s1, data/s2, data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see Section 2.9.1, “Initializing the Data Directory”.

**Warning**

Do not use `-initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see Section 20.6, “Group Replication Security”.

### Configuration of Local Group Replication Members

When you are following Section 20.2.1.2, “Configuring an Instance for Group Replication”, you need to add configuration for the data directories added in the previous section. For example:

```ini
[mysqld]
# server configuration
dataDir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-8.4/
port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

**Note**

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

Group Replication requires a network connection between the members, which means that each member must be able to resolve the network address of all of the other members. For example in this tutorial all three instances run on one machine, so to ensure that the members can contact each other you could add a line to the option file such as `report_host=127.0.0.1`.

Then each member needs to be able to connect to the other members on their `group_replication_local_address`. For example in the option file of member s1 add:

```ini
group_replication_local_address= "127.0.0.1:24901"
group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
```

This configures s1 to use port 24901 for internal group communication with seed members. For each server instance you want to add to the group, make these changes in the option file of the member. For each member you must ensure a unique address is specified, so use a unique port per instance for `group_replication_local_address`. Usually you want all members to be able to serve as seeds for members that are joining the group and have not got the transactions processed by the group. In this case, add all of the ports to `group_replication_group_seeds` as shown above.

The remaining steps of Section 20.2.1, “Deploying Group Replication in Single-Primary Mode” apply equally to a group which you have deployed locally in this way.

### 20.3 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

#### 20.3.1 Group Replication Requirements

- **Infrastructure**
Server instances that you want to use for Group Replication must satisfy the following requirements.

### Infrastructure

- **InnoDB Storage Engine.** Data must be stored in the InnoDB transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, InnoDB provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication. The use of other storage engines, including the temporary MEMORY storage engine, might cause errors in Group Replication. Convert any tables in other storage engines to use InnoDB before using the instance with Group Replication. You can prevent the use of other storage engines by setting the `disabled_storage_engines` system variable on group members, for example:

  ```
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"
  ```

- **Primary Keys.** Every table that is to be replicated by the group must have a defined primary key, or primary key equivalent where the equivalent is a non-null unique key. Such keys are required as a unique identifier for every row within a table, enabling the system to determine which transactions conflict by identifying exactly which rows each transaction has modified. Group Replication has its own built-in set of checks for primary keys or primary key equivalents, and does not use the checks carried out by the `sql_require_primary_key` system variable. You may set `sql_require_primary_key=ON` for a server instance where Group Replication is running, and you may set the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option of the `CHANGE REPLICATION SOURCE TO` statement to `ON` for a Group Replication channel. However, be aware that you might find some transactions that are permitted under Group Replication's built-in checks are not permitted under the checks carried out when you set `sql_require_primary_key=ON` or `REQUIRE_TABLE_PRIMARY_KEY_CHECK=ON`.

- **Network Performance.** MySQL Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other. The performance and stability of a group can be impacted by both network latency and network bandwidth. Bi-directional communication must be maintained at all times between all group members. If either inbound or outbound communication is blocked for a server instance (for example, by a firewall, or by connectivity issues), the member cannot function in the group, and the group members (including the member with issues) might not be able to report the correct member status for the affected server instance.

  You can use a network infrastructure based on IPv4, IPv6, or a mix of the two, for TCP communication between remote Group Replication servers. There is also nothing preventing Group Replication from operating over a virtual private network (VPN).

  Where Group Replication server instances are co-located and share a local group communication engine (XCom) instance, a dedicated input channel with lower overhead is used for communication where possible instead of the TCP socket. For certain Group Replication tasks that require communication between remote XCom instances, such as joining a group, the TCP network is still used, so network performance influences the group's performance.

### Server Instance Configuration

The following options must be configured as shown on server instances that are members of a group.

- **Unique Server Identifier.** Use the `server_id` system variable to configure the server with a unique server ID, as required for all servers in replication topologies. The server ID must be a positive integer between 1 and \(2^{32}-1\), and it must be different from every other server ID in use by any other server in the replication topology.
Group Replication Requirements

- **Binary Log Active.** In MySQL 8.4, binary logging is enabled by default. You can optionally specify the names of the binary log files using `--log-bin=[log_file_name]`. Group Replication replicates the binary log's contents, therefore the binary log needs to be on for it to operate. See Section 7.4.4, “The Binary Log”.

- **Replica Updates Logged.** Set `log_replica_updates=ON` if it is not already enabled. (In MySQL 8.4, this is the default.) Group members need to log transactions that are received from their donors at joining time and applied through the replication applier, and to log all transactions that they receive and apply from the group. This enables Group Replication to carry out distributed recovery by state transfer from an existing group member’s binary log.

- **Binary Log Row Format.** Set `binlog_format=ROW` if necessary; in MySQL 8.4, this is the default. Group Replication relies on the row-based replication format to propagate changes consistently among the servers in the group, and extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. The setting for `REQUIRE_ROW_FORMAT` is automatically added to Group Replication's channels to enforce the use of row-based replication when the transactions are applied. See Section 19.2.1, “Replication Formats” and Section 19.3.3, “Replication Privilege Checks”.

- **Global Transaction Identifiers On.** Set `gtid_mode=ON` and `enforce_gtid_consistency=ON`. These settings are not the defaults. GTID-based replication is required for Group Replication, which uses global transaction identifiers to track the transactions that have been committed on every server instance in the group. See Section 19.1.3, “Replication with Global Transaction Identifiers”.

- **Default Table Encryption.** Set `default_table_encryption` to the same value on all group members. Default schema and tablespace encryption can be either enabled (ON) or disabled (OFF, the default) as long as the setting is the same on all members.

- **Lower Case Table Names.** Set `lower_case_table_names` to the same value on all group members. A setting of 1 is correct for the use of the InnoDB storage engine, which is required for Group Replication. Note that this setting is not the default on all platforms.

- **Multithreaded Appliers.** Group Replication members can be configured as multithreaded replicas, enabling transactions to be applied in parallel. All replicas are configured as multithreaded by default. A nonzero value for `replica_parallel_workers` enables the multithreaded applier on the member. The default is 4 parallel applier threads; up to 1024 parallel applier threads can be specified.

  Setting `replica_parallel_workers=0` disables parallel execution and gives the replica a single applier thread and no coordinator thread. With that setting, the `replica_parallel_type` and `replica_preserve_commit_order` options have no effect and are ignored. If parallel execution is disabled when GTIDs are in use on a replica, the replica actually uses one parallel worker, to take advantage of the method for retrying transactions without accessing the file positions. However, this behavior does not change anything for the user.

- **Detached XA transactions.** MySQL 8.4 and later supports detached XA transactions. A detached transaction is one which, once prepared, is no longer connected to the current session. This happens automatically as part of executing `XA PREPARE`. The prepared XA transaction can be committed or rolled back by another connection, and the current session can then initiate another XA transaction or local transaction without waiting for the transaction that was just prepared to complete.

  When detached XA transaction support is enabled (`xa_detach_on_prepare = ON`) it is possible for any connection to this server to list (using `XA RECOVER`), roll back, or commit any prepared XA transaction. In addition, you cannot use temporary tables within detached XA transactions.

  You can disable support for detached XA transactions by setting `xa_detach_on_prepare` to `OFF`, but this is not recommended. In particular, if this server is being set up as an instance in MySQL group replication, you should leave this variable set to its default value (`ON`).

  See Section 15.3.8.2, “XA Transaction States”, for more information.
20.3.2 Group Replication Limitations

- Limit on Group Size
- Limits on Transaction Size

The following known limitations exist for Group Replication. Note that the limitations and issues described for multi-primary mode groups can also apply in single-primary mode clusters during a failover event, while the newly elected primary flushes out its applier queue from the old primary.

Tip
Group Replication is built on GTID based replication, therefore you should also be aware of Section 19.1.3.7, "Restrictions on Replication with GTIDs".

- `--upgrade=MINIMAL` option. Group Replication cannot be started following a MySQL Server upgrade that uses the MINIMAL option (`--upgrade=MINIMAL`), which does not upgrade system tables on which the replication internals depend.

- Gap Locks. Group Replication's certification process for concurrent transactions does not take into account gap locks, as information about gap locks is not available outside of InnoDB. See Gap Locks for more information.

Note
For a group in multi-primary mode, unless you rely on REPEATABLE READ semantics in your applications, we recommend using the READ COMMITTED isolation level with Group Replication. InnoDB does not use gap locks in READ COMMITTED, which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication. For a group in single-primary mode, only the primary accepts writes, so the READ COMMITTED isolation level is not important to Group Replication.

- Table Locks and Named Locks. The certification process does not take into account table locks (see Section 15.3.6, "LOCK TABLES and UNLOCK TABLES Statements") or named locks (see `GET_LOCK`).

- Binary Log Checksums. Group Replication in MySQL 8.4 supports checksums, so group members may use the default setting `binlog_checksum=CRC32`. The setting for `binlog_checksum` does not have to be the same for all members of a group.

When checksums are available, Group Replication does not use them to verify incoming events on the `group_replication_applier` channel, because events are written to that relay log from multiple sources and before they are actually written to the originating server's binary log, which is when a checksum is generated. Checksums are used to verify the integrity of events on the `group_replication_recovery` channel and on any other replication channels on group members.

- SERIALIZABLE Isolation Level. SERIALIZABLE isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to SERIALIZABLE configures Group Replication to refuse to commit the transaction.

- Concurrent DDL versus DML Operations. Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.

- Foreign Keys with Cascading Constraints. Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables
with multi-level foreign key dependencies, specifically tables that have defined CASCADING foreign key constraints. This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting `group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

- **Multi-primary Mode Deadlock.** When a group is operating in multi-primary mode, `SELECT .. FOR UPDATE` statements can result in a deadlock. This is because the lock is not shared across the members of the group, therefore the expectation for such a statement might not be reached.

- **Replication Filters.** Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

- **Encrypted Connections.** Support for the TLSv1.3 protocol is available in MySQL, provided that it was compiled using OpenSSL 1.1.1 or higher. Group Replication supports TLSv1.3, where it can be used for group communication connections and distributed recovery connections.

  `group_replication_recovery_tls_version` and `group_replication_recovery_tls_ciphersuites` can be used to configure client support for any selection of ciphersuites, including only non-default ciphersuites if desired. See Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

- **Cloning Operations.** Group Replication initiates and manages cloning operations for distributed recovery, but group members that have been set up to support cloning may also participate in cloning operations that a user initiates manually. You can initiate a cloning operation manually if the operation involves a group member on which Group Replication is running, provided that the cloning operation does not remove and replace the data on the recipient. The statement to initiate the cloning operation must therefore include the DATA DIRECTORY clause if Group Replication is running. See Cloning for Other Purposes.

### Limit on Group Size

The maximum number of MySQL servers that can be members of a single replication group is 9. If further members attempt to join the group, their request is refused. This limit has been identified from testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.

### Limits on Transaction Size

If an individual transaction results in message contents which are large enough that the message cannot be copied between group members over the network within a 5-second window, members can be suspected of having failed, and then expelled, just because they are busy processing the transaction. Large transactions can also cause the system to slow due to problems with memory allocation. To avoid these issues use the following mitigations:

- If unnecessary expulsions occur due to large messages, use the system variable `group_replication_member_expel_timeout` to allow additional time before a member under suspicion of having failed is expelled. You can allow up to an hour after the initial 5-second detection period before a suspect member is expelled from the group. An additional 5 seconds is allowed by default.

- Where possible, try and limit the size of your transactions before they are handled by Group Replication. For example, split up files used with `LOAD DATA` into smaller chunks.
Monitoring Group Replication

- Use the system variable `group_replication_transaction_size_limit` to specify a maximum transaction size that the group accepts. The default maximum transaction size is 150000000 bytes (approximately 143 MB); transactions above this size are rolled back and are not sent to Group Replication's Group Communication System (GCS) for distribution to the group. Adjust the value of this variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size.

- Use the system variable `group_replication_compression_threshold` to specify a message size above which compression is applied. This system variable defaults to 1000000 bytes (1 MB), so large messages are automatically compressed. Compression is carried out by Group Replication's Group Communication System (GCS) when it receives a message that was permitted by the `group_replication_transaction_size_limit` setting but exceeds the `group_replication_compression_threshold` setting. For more information, see Section 20.7.4, “Message Compression”.

- Use the system variable `group_replication_communication_max_message_size` to specify a message size above which messages are fragmented. This system variable defaults to 10485760 bytes (10 MiB), so large messages are automatically fragmented. GCS carries out fragmentation after compression if the compressed message still exceeds the `group_replication_communication_max_message_size` limit. For more information, see Section 20.7.5, “Message Fragmentation”.

The maximum transaction size, message compression, and message fragmentation can all be deactivated by specifying a zero value for the relevant system variable. If you have deactivated all these safeguards, the upper size limit for a message that can be handled by the applier thread on a member of a replication group is the value of the member's `replica_max_allowed_packet` system variable, which has a default and maximum value of 1073741824 bytes (1 GB). A message that exceeds this limit fails when the receiving member attempts to handle it. The upper size limit for a message that a group member can originate and attempt to transmit to the group is 4294967295 bytes (approximately 4 GB). This is a hard limit on the packet size that is accepted by the group communication engine for Group Replication (XCom, a Paxos variant), which receives messages after GCS has handled them. A message that exceeds this limit fails when the originating member attempts to broadcast it.

20.4 Monitoring Group Replication

You can use the MySQL Performance Schema to monitor Group Replication. These Performance Schema tables display information specific to Group Replication:

- `replication_group_member_stats`: See Section 20.4.4, “The replication_group_member_stats Table”.

- `replication_group_members`: See Section 20.4.3, “The replication_group_members Table”.

- `replication_group_communication_information`: See Section 29.12.11.15, “The replication_group_communication_information Table”.

These Performance Schema replication tables also show information relating to Group Replication:

- `replication_connection_status` shows information regarding Group Replication, such as transactions received from the group and queued in the applier queue (relay log).

- `replication_applier_status` shows the states of channels and threads relating to Group Replication. These can also be used to monitor what individual worker threads are doing.

Replication channels created by the Group Replication plugin are listed here:

- `group_replication_recovery`: Used for replication changes related to distributed recovery.

- `group_replication_applier`: Used for the incoming changes from the group, to apply transactions coming directly from the group.
GTIDs and Group Replication

For information about system variables affecting Group Replication, see Section 20.9.1, “Group Replication System Variables”. See Section 20.9.2, “Group Replication Status Variables”, for status variables providing information about Group Replication.

Messages relating to Group Replication lifecycle events other than errors are classified as system messages; these are always written to the replication group member’s error log. You can use this information to review the history of a given server’s membership in a replication group.

Some lifecycle events that affect the whole group are logged on every group member, such as a new member entering ONLINE status in the group or a primary election. Other events are logged only on the member where they take place, such as super read only mode being enabled or disabled on the member, or the member leaving the group. A number of lifecycle events that can indicate an issue if they occur frequently are logged as warning messages, including a member becoming unreachable and then reachable again, and a member starting distributed recovery by state transfer from the binary log or by a remote cloning operation.

Note
If you are monitoring one or more secondary instances using mysqladmin, you should be aware that a FLUSH STATUS statement executed by this utility creates a GTID event on the local instance which may impact future group operations.

20.4.1 GTIDs and Group Replication

Group Replication uses GTIDs (global transaction identifiers) to track exactly which transactions have been committed on every server instance. The settings gtid_mode=ON and enforce_gtid_consistency=ON are required on all group members. Incoming transactions from clients are assigned a GTID by the group member that receives them. Any replicated transactions that are received by group members on asynchronous replication channels from source servers outside the group retain the GTIDs that they have when they arrive on the group member.

The GTIDs that are assigned to incoming transactions from clients use the group name specified by the group_replication_group_name system variable as the UUID part of the identifier, rather than the server UUID of the individual group member that received the transaction. All the transactions received directly by the group can therefore be identified and are grouped together in GTID sets, and it does not matter which member originally received them. Each group member has a block of consecutive GTIDs reserved for its use, and when these are consumed it reserves more. The group_replication_gtid_assignment_block_size system variable sets the size of the blocks, with a default of 1 million GTIDs in each block.

View change events (View_change_log_event), which are generated by the group itself when a new member joins, are given GTIDs when they are recorded in the binary log. By default, the GTIDs for these events also use the group name specified by the group_replication_group_name system variable as the UUID part of the identifier. You can set the Group Replication system variable group_replication_view_change_uuid to use an alternative UUID in the GTIDs for view change events, so that they are easy to distinguish from transactions received by the group from clients. This can be useful if your setup allows for failover between groups, and you need to identify and discard transactions that were specific to the backup group. The alternative UUID must be different from the server UUIDs of the members. It must also be different from any UUIDs in the GTIDs applied to anonymous transactions using the ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS option of the CHANGE REPLICATION SOURCE TO statement.

GTID_ONLY=1, REQUIRE_ROW_FORMAT = 1, and SOURCE_AUTO_POSITION = 1 are applied for the Group Replication channels group_replication_applier and group_replication_recovery. The settings are made automatically on the Group Replication channels when they are created, or when a member server in a replication group is upgraded. These options are normally set using a CHANGE REPLICATION SOURCE TO statement, but note that you cannot disable them for a Group Replication channel. With these options set, the group member does not persist file names and file
positions in the replication metadata repositories for these channels. GTID auto-positioning and GTID auto-skip are used to locate the correct receiver and applier positions when necessary.

**Extra Transactions**

If a joining member has transactions in its GTID set that are not present on the existing members of the group, it is not allowed to complete the distributed recovery process, and cannot join the group. If a remote cloning operation was carried out, these transactions would be deleted and lost, because the data directory on the joining member is erased. If state transfer from a donor's binary log was carried out, these transactions could conflict with the group's transactions.

Extra transactions might be present on a member if an administrative transaction is carried out on the instance while Group Replication is stopped. To avoid introducing new transactions in that way, always set the value of the `sql_log_bin` system variable to `OFF` before issuing administrative statements, and back to `ON` afterwards:

```
SET SQL_LOG_BIN=0;
<administrator action>
SET SQL_LOG_BIN=1;
```

Setting this system variable to `OFF` means that the transactions that occur from that point until you set it back to `ON` are not written to the binary log and do not have GTIDs assigned to them.

If an extra transaction is present on a joining member, check the binary log for the affected server to see what the extra transaction actually contains. The safest method to reconcile the joining member's data and GTID set with the members currently in the group is to use MySQL's cloning functionality to transfer the content from a server in the group to the affected server. For instructions to do this, see Section 7.6.7.3, “Cloning Remote Data”. If the transaction is required, rerun it after the member has successfully rejoined.

### 20.4.2 Group Replication Server States

The state of a Group Replication group member shows its current role in the group. The Performance Schema table `replication_group_members` shows the state for each member in a group. If the group is fully functional and all members are communicating properly, all members report the same state for all other members. However, a member that has left the group or is part of a network partition cannot report accurate information on the other servers. In this situation, the member does not attempt to guess the status of the other servers, and instead reports them as unreachable.

A group member can be in the following states:

- **ONLINE**
  The server is an active member of a group and in a fully functioning state. Other group members can connect to it, as can clients if applicable. A member is only fully synchronized with the group, and participating in it, when it is in the ONLINE state.

- **RECOVERING**
  The server has joined a group and is in the process of becoming an active member. Distributed recovery is currently taking place, where the member is receiving state transfer from a donor using a remote cloning operation or the donor's binary log. This state is

  For more information, see Section 20.5.4, “Distributed Recovery”.

- **OFFLINE**
  The Group Replication plugin is loaded but the member does not belong to any group. This status may briefly occur while a member is joining or rejoining a group.

- **ERROR**
  The member is in an error state and is not functioning correctly as a group member. A member can enter error state either while applying transactions or during the recovery phase. A member in
this state does not participate in the group's transactions. For more information on possible reasons for error states, see Section 20.7.7, “Responses to Failure Detection and Network Partitioning”.

Depending on the exit action set by `group_replication_exit_state_action`, the member is in read-only mode (`super_read_only=ON`) and could also be in offline mode (`offline_mode=ON`). Note that a server in offline mode following the `OFFLINE_MODE` exit action is displayed with `ERROR` status, not `OFFLINE`. A server with the exit action `ABORT_SERVER` shuts down and is removed from the view of the group. For more information, see Section 20.7.7.4, “Exit Action”.

While a member is joining or rejoining a replication group, its status can be displayed as `ERROR` before the group completes the compatibility checks and accepts it as a member.

**UNREACHABLE**

The local failure detector suspects that the member cannot be contacted, because the group's messages are timing out. This can happen if a member is disconnected involuntarily, for example. If you see this status for other servers, it can also mean that the member where you query this table is part of a partition, where a subset of the group's servers can contact each other but cannot contact the other servers in the group. For more information, see Section 20.7.8, “Handling a Network Partition and Loss of Quorum”.

See Section 20.4.3, “The replication_group_members Table” for an example of the Performance Schema table contents.

### 20.4.3 The replication_group_members Table

The `performance_schema.replication_group_members` table is used for monitoring the status of the different server instances that are members of the group. The information in the table is updated whenever there is a view change, for example when the configuration of the group is dynamically changed when a new member joins. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. This table can be used to get a high level view of the state of a replication group, for example by issuing:

```sql
SELECT * FROM performance_schema.replication_group_members;
```

<table>
<thead>
<tr>
<th>CHANNEL_NAME</th>
<th>MEMBER_ID</th>
<th>MEMBER_HOST</th>
<th>MEMBER_PORT</th>
<th>MEMBER_STATE</th>
<th>MEMBER_ROLE</th>
<th>MEMBER_VERSION</th>
<th>MEMBER_COMMUNICATION_STACK</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_replication_applier</td>
<td>d391e9ee-2691-11ec-bf61-00059a3c7a00</td>
<td>example1</td>
<td>4410</td>
<td>ONLINE</td>
<td>PRIMARY</td>
<td>8.4.0</td>
<td>XCom</td>
</tr>
<tr>
<td>group_replication_applier</td>
<td>e059ce5c-2691-11ec-8632-00059a3c7a00</td>
<td>example2</td>
<td>4420</td>
<td>ONLINE</td>
<td>SECONDARY</td>
<td>8.4.0</td>
<td>XCom</td>
</tr>
<tr>
<td>group_replication_applier</td>
<td>ecd9ad06-2691-11ec-91c7-00059a3c7a00</td>
<td>example3</td>
<td>4430</td>
<td>ONLINE</td>
<td>SECONDARY</td>
<td>8.4.0</td>
<td>XCom</td>
</tr>
</tbody>
</table>

3 rows in set (0.0007 sec)

Based on this result we can see that the group consists of three members. Shown in the table is each member’s `server_uuid`, as well as the member's host name and port number, which clients use to connect to it. The `MEMBER_STATE` column shows one of the Section 20.4.2, “Group Replication Server States”, in this case it shows that all three members in this group are `ONLINE`, and the `MEMBER_ROLE` column shows that there are two secondaries, and a single primary. Therefore this group must be running in single-primary mode. The `MEMBER_VERSION` column can be useful when you are upgrading a group and are combining members running different MySQL versions. The `MEMBER_COMMUNICATION_STACK` column shows the communication stack used for the group.

For more information about the `MEMBER_HOST` value and its impact on the distributed recovery process, see Section 20.2.1.3, “User Credentials For Distributed Recovery”.

3574
20.4.4 The replication_group_member_stats Table

Each member in a replication group certifies and applies transactions received by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on.

The `performance_schema.replication_group_member_stats` table provides group-level information related to the certification process, and also statistics for the transactions received and originated by each individual member of the replication group. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. Note that refreshing of statistics for remote members is controlled by the message period specified in the `group_replication_flow_control_period` option, so these can differ slightly from the locally collected statistics for the member where the query is made. To use this table to monitor a Group Replication member, issue the following statement:

```sql
SELECT * FROM performance_schema.replication_group_member_stats
```

You can also use the following statement:

```sql
TABLE performance_schema.replication_group_member_stats
```

These columns are important for monitoring the performance of the members connected in the group. Suppose that one of the group's members always reports a large number of transactions in its queue compared to other members. This means that the member is delayed and is not able to keep up to date with the other members of the group. Based on this information, you could decide to either remove the member from the group, or delay the processing of transactions on the other members of the group in order to reduce the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin, see Section 20.7.2, “Flow Control”.

20.5 Group Replication Operations

This section explains common operations for managing groups.

20.5.1 Configuring an Online Group

You can configure an online group while Group Replication is running by using a set of functions, which rely on a group action coordinator. These functions are installed by the Group Replication plugin. This section describes how changes are made to a running group, and the available functions.

**Important**

For the coordinator to be able to configure group wide actions on a running group, all members must have the functions installed.

To use the functions, connect to a member of the running group and invoke the function with the `SELECT` statement. The Group Replication plugin processes the action and its parameters and the coordinator sends it to all members which are visible to the member where you invoked the function. If the action is accepted, all members execute the action and send a termination message when completed. Once all members declare the action as finished, the invoking member returns the result to the client.

When configuring a whole group, the distributed nature of the operations means that they interact with many processes of the Group Replication plugin, and therefore you should observe the following:

**You can issue configuration operations everywhere.** If you want to make member A the new primary you do not need to invoke the operation on member A. All operations are sent and executed in a coordinated way on all group members. Also, this distributed execution of an operation has a different ramification: if the invoking member dies, any already running configuration process continues to run.
on other members. In the unlikely event that the invoking member dies, you can still use the monitoring features to ensure other members complete the operation successfully.

**All members must be online.** To simplify the migration or election processes and guarantee they are as fast as possible, the group must not contain any member currently in the distributed recovery process, otherwise the configuration action is rejected by the member where you issue the statement.

**No members can join a group during a configuration change.** Any member that attempts to join the group during a coordinated configuration change leaves the group and cancels its join process.

**Only one configuration at once.** A group which is executing a configuration change cannot accept any other group configuration change, because concurrent configuration operations could lead to member divergence.

### 20.5.1.1 Changing the Primary

This section explains how to change which member of a single-primary group is the primary, using the `group_replication_set_as_primary()` function, which can be can be run on any member of the group. When this is done, the current primary becomes a read-only secondary, and the specified group member becomes the read-write primary; this replaces the usual primary election process as described in Section 20.1.3.1, “Single-Primary Mode”.

If a standard source-to-replica replication channel is running on the existing primary member in addition to the Group Replication channels, you must stop that replication channel before you can change the primary member. You can identify the current primary using the `MEMBER_ROLE` column in the Performance Schema `replication_group_members` table.

If all members are not running the same MySQL Server version, you can specify a new primary member that is running the lowest MySQL Server version in the group only. This safeguard is applied to ensure the group maintains compatibility with new functions.

Any uncommitted transactions that the group is waiting on must be committed, rolled back, or terminated before the operation can complete. You can specify a timeout from 0 seconds (immediately) up to 3600 seconds (60 minutes) for transactions that are running when you use the function. There is no default setting for the timeout, so if you do not set it, there is no upper limit to the wait time, and new transactions can start during that time.

When the timeout expires, for any transactions that did not yet reach their commit phase, the client session is disconnected so that the transaction does not proceed. Transactions that reached their commit phase are allowed to complete. When you set a timeout, it also prevents new transactions starting on the primary from that point on. Explicitly defined transactions (with a `START TRANSACTION` or `BEGIN` statement) are subject to the timeout, disconnection, and incoming transaction blocking even if they do not modify any data. To allow inspection of the primary while the function is operating, single statements that do not modify data, as listed in Permitted Queries Under Consistency Rules, are permitted to proceed.

Pass in the `server_uuid` of the member which you want to become the new primary of the group by issuing the following statement:

```sql
SELECT group_replication_set_as_primary(member_uuid);
```

You can add a timeout as shown here:

```sql
SELECT group_replication_set_as_primary('00371d66-3c45-11ea-804b-080027337932', 300)
```

To check the status of the timeout, use the `PROCESSLIST_INFO` column in the Performance Schema `threads` table, like this:

```sql
mysql> SELECT NAME, PROCESSLIST_INFO FROM performance_schema.threads
    -> WHERE NAME="thread/group_rpl/THD_transaction_monitor"G
+--------------------------------+--------------------------------------------------+
| NAME: thread/group_rpl/THD_transaction_monitor | PROCESSLIST_INFO: Group replication transaction monitor: Stopped client connections |
+--------------------------------+--------------------------------------------------+
```

3576
The status shows when the transaction monitoring thread has been created, when new transactions have been stopped, when the client connections with uncommitted transactions have been disconnected, and finally, when the process is complete and new transactions are allowed again.

While the action runs, you can check its progress by issuing the statement shown here:

```
mysql> SELECT event_name, work_completed, work_estimated
    > FROM performance_schema.events_stages_current
    > WHERE event_name LIKE "%stage/group_rpl%"
*************************** 1. row ***************************
<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>work_completed</th>
<th>work_estimated</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage/group_rpl/Primary Election: Waiting for members to turn on super_read_only</td>
<td>3</td>
<td>5</td>
</tr>
</tbody>
</table>
```

### 20.5.1.2 Changing the Group Mode

This section explains how to change the mode which a group is running in, either single or multi-primary. The functions used to change a group's mode can be run on any member.

#### Changing to Single-Primary Mode

Use the `group_replication_switch_to_single_primary_mode()` function to change a group running in multi-primary mode to single-primary mode by issuing:

```
SELECT group_replication_switch_to_single_primary_mode()
```

When you change to single-primary mode, strict consistency checks are also disabled on all group members, as required in single-primary mode (`group_replication_enforce_update_everywhere_checks=OFF`).

If no string is passed in, the election of the new primary in the resulting single-primary group follows the election policies described in Section 20.1.3.1, "Single-Primary Mode". To override the election process and configure a specific member of the multi-primary group as the new primary in the process, get the server_uuid of the member and pass it to `group_replication_switch_to_single_primary_mode()`. For example, issue:

```
SELECT group_replication_switch_to_single_primary_mode(member_uuid);
```

If you invoke the function on a member running a MySQL Server version from 8.0.17, and all members are running MySQL Server version 8.0.17 or higher, you can only specify a new primary member that is running the lowest MySQL Server version in the group, based on the patch version. This safeguard is applied to ensure the group maintains compatibility with new functions. If you do not specify a new primary member, the election process considers the patch version of the group members.

If any member is running a MySQL Server version between MySQL 8.0.13 and MySQL 8.0.16, this safeguard is not enforced for the group and you can specify any new primary member, but it is recommended to select a primary that is running the lowest MySQL Server version in the group. If you do not specify a new primary member, the election process considers only the major version of the group members.

While the action runs, you can check its progress by issuing:

```
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE event_name LIKE "%stage/group_rpl%"
```

#### Changing to Multi-Primary Mode

Use the `group_replication_switch_to_multi_primary_mode()` function to change a group running in single-primary mode to multi-primary mode by issuing:
### Configuring an Online Group

**SELECT group_replication_switch_to_multi_primary_mode()**

After some coordinated group operations to ensure the safety and consistency of your data, all members which belong to the group become primaries.

When you change a group that was running in single-primary mode to run in multi-primary mode, members running MySQL 8.0.17 or higher are automatically placed in read-only mode if they are running a higher MySQL server version than the lowest version present in the group. Members running MySQL 8.0.16 or lower do not carry out this check, and are always placed in read-write mode.

While the action runs, you can check its progress by issuing:

```
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE event_name LIKE "%stage/group_rpl%"
```

<table>
<thead>
<tr>
<th>event_name</th>
<th>work_completed</th>
<th>work_estimated</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage/group_rpl/Multi-primary Switch: applying buffered transactions</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

### 20.5.1.3 Using Group Replication Group Write Consensus

This section explains how to inspect and configure the maximum number of consensus instances at any time for a group. This maximum is referred to as the event horizon for a group, and is the maximum number of consensus instances that the group can execute in parallel. This enables you to fine-tune the performance of your Group Replication deployment. For example, the default value of 10 is suitable for a group running on a LAN, but for groups operating over a slower network such as a WAN, increase this number to improve performance.

#### Inspecting a Group's Write Concurrency

Use the `group_replication_get_write_concurrency()` function to inspect a group's event horizon value at runtime by issuing:

```
SELECT group_replication_get_write_concurrency();
```

#### Configuring a Group's Write Concurrency

Use the `group_replication_set_write_concurrency()` function to set the maximum number of consensus instances that the system can execute in parallel by issuing:

```
SELECT group_replication_set_write_concurrency(instances);
```

where `instances` is the new maximum number of consensus instances. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function.

### 20.5.1.4 Setting a Group's Communication Protocol Version

Group Replication in MySQL 8.4 uses the concept of a group communication protocol whose version can be managed explicitly, and set to accommodate the oldest MySQL Server version that you want the group to support. This enables groups to be formed from members using different MySQL Server versions while ensuring backward compatibility.

- MySQL 5.7.14 and later allows compression of messages (see Section 20.7.4, “Message Compression”).
- MySQL 8.0.16 and later also allows fragmentation of messages (see Section 20.7.5, “Message Fragmentation”).
- MySQL 8.0.27 and later also allow the group communication engine to operate with a single consensus leader when the group is in single-primary mode and `group_replication_paxos_single_leader` is set to true (see Section 20.7.3, “Single Consensus Leader”).
Configuring an Online Group

All members of the group must use the same communication protocol version, so that group members can be at different MySQL Server releases but only send messages that can be understood by all group members.

A MySQL server at version X can only join and reach ONLINE status in a replication group if the group's communication protocol version is less than or equal to X. When a new member joins a replication group, it checks the communication protocol version that is announced by the existing members of the group. If the joining member supports that version, it joins the group and uses the communication protocol that the group has announced, even if the member supports additional communication capabilities. If the joining member does not support the communication protocol version, it is expelled from the group.

If two members attempt to join in the same membership change event, they can only join if the communication protocol version for both members is already compatible with the group's communication protocol version. Members with different communication protocol versions from the group must join in isolation. For example:

- One MySQL Server 8.0.16 instance can successfully join a group that uses the communication protocol version 5.7.24.
- One MySQL Server 5.7.24 instance cannot successfully join a group that uses the communication protocol version 8.0.16.
- Two MySQL Server 8.0.16 instances cannot simultaneously join a group that uses the communication protocol version 5.7.24.
- Two MySQL Server 8.0.16 instances can simultaneously join a group that uses the communication protocol version 8.0.16.

You can inspect the communication protocol in use by a group by using the `group_replication_get_communication_protocol()` function, which returns the oldest MySQL Server version that the group supports. All existing members of the group return the same communication protocol version. For example:

```
SELECT group_replication_get_communication_protocol();
+------------------------------------------------+
| group_replication_get_communication_protocol() |
+------------------------------------------------+
| 8.0.16                                         |
+------------------------------------------------+
```

Note that the `group_replication_get_communication_protocol()` function returns the minimum MySQL version that the group supports, which might differ from the version number that was passed to the `group_replication_set_communication_protocol()` function, and from the MySQL Server version that is installed on the member where you use the function.

If you need to change the communication protocol version of a group so that members at earlier releases can join, use the `group_replication_set_communication_protocol()` function to specify the MySQL Server version of the oldest member that you want to allow. This makes the group fall back to a compatible communication protocol version if possible. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function, and all existing group members must be online when you issue the statement, with no loss of majority. For example:

```
SELECT group_replication_set_communication_protocol("5.7.25");
```

If you upgrade all the members of a replication group to a new MySQL Server release, the group's communication protocol version is not automatically upgraded to match. If you no longer need to support members at earlier releases, you can use the `group_replication_set_communication_protocol()` function to set the communication protocol version to the new MySQL Server version to which you have upgraded the members. For example:
The `group_replication_set_communication_protocol()` function is implemented as a group action, so it is executed at the same time on all members of the group. The group action starts buffering messages and waits for delivery of any outgoing messages that were already in progress to complete, then changes the communication protocol version and sends the buffered messages. If a member attempts to join the group at any time after you change the communication protocol version, the group members announce the new protocol version.

MySQL InnoDB cluster automatically and transparently manages the communication protocol versions of its members, whenever the cluster topology is changed using AdminAPI operations. An InnoDB cluster always uses the most recent communication protocol version that is supported by all the instances that are currently part of the cluster or joining it. For details, see InnoDB Cluster and Group Replication Protocol.

### 20.5.1.5 Configuring Member Actions

Group Replication has the ability to set actions for the members of a group to take in specified situations. Member actions can be enabled and disabled individually using functions. The member actions configuration for a server can also be reset to the default after it has left the group.

Administrators (with the `GROUP_REPLICATION_ADMIN` privilege) can configure a member action on the group’s primary using the `group_replication_enable_member_action` or `group_replication_disable_member_action` function. The member actions configuration, consisting of all the member actions and whether they are enabled or disabled, is then propagated to other group members and joining members using Group Replication’s group messages. All group members therefore have the same member actions configuration. You can also configure member actions on a server that is not part of a group, as long as the Group Replication plugin is installed. In that case, the member actions configuration is not propagated to any other servers.

If the server where you use the functions to configure a member action is part of a group, it must be the current primary in a group in single-primary mode, and it must be part of the majority. The configuration change is tracked internally by Group Replication, but it is not given a GTID and is not written to the binary log, so it is not propagated to any servers outside the group, such as downstream replicas. Group Replication increments the version number for its member actions configuration each time a member action is enabled or disabled.

The member actions configuration is propagated to members as follows:

- When starting a group, the member actions configuration of the server that bootstraps the group becomes the configuration for the group.
- If a group’s lowest MySQL Server version supports member actions, joining members receive the group’s member actions configuration during the state exchange process that takes place when they join. In that case, the joining member replaces its own member actions configuration with the group’s.
- If a joining member that supports member actions joins a group where the lowest MySQL Server version does not support member actions, it does not receive a member actions configuration when it joins. In that case, the joining member resets its own configuration to the default.

A member that does not support member actions cannot join a group that has a member actions configuration, because its MySQL Server version is lower than the lowest version that the existing group members are running.

The Performance Schema table `replication_group_member_actions` lists the member actions that are available in the configuration, the events that trigger them, and whether or not they are currently enabled. Member actions have a priority from 1 to 100, with lower values being actioned first. If an error occurs when the member action is being carried out, the failure of the member action can be logged but otherwise ignored. If the failure of the member action is considered critical, it can
be handled according to the policy specified by the `group_replication_exit_state_action` system variable.

The `mysql.replication_group_configuration_version` table, which can be viewed using the Performance Schema table `replication_group_configuration_version`, records the current version of the member actions configuration. Whenever a member action is enabled or disabled using the functions, the version number is incremented.

The `group_replication_reset_member_actions` function can only be used on a server that is not part of a group. It resets the member actions configuration to the default settings, and resets its version number to 1. The server must be writeable (with the `read_only` system variable set to `OFF`) and have the Group Replication plugin installed. You can use this function to remove the member actions configuration that a server used when it was part of a group, if you intend to use it as a standalone server with no member actions or different member actions.

**Member action: `mysql_disable_super_read_only_if_primary`**

The member action `mysql_disable_super_read_only_if_primary` can be configured to make a group in single-primary mode stay in super read-only mode when a new primary is elected, so that the group only accepts replicated transactions and does not accept any direct writes from clients. This setup means that when a group’s purpose is to provide a secondary backup to another group for disaster tolerance, you can ensure that the secondary group remains synchronized with the first.

By default, super read-only mode is disabled on the primary when it is elected, so that the primary becomes read-write, and accepts updates from a replication source server and from clients. This is the situation when the member action `mysql_disable_super_read_only_if_primary` is enabled, which is its default setting. If you set the action to disabled using the `group_replication_disable_member_action` function, the primary remains in super read-only mode after election. In this state, it does not accept updates from any clients, even users who have the `CONNECTION_ADMIN` or `SUPER` privilege. It does continue to accept updates performed by replication threads.

### 20.5.2 Restarting a Group

Group Replication is designed to ensure that the database service is continuously available, even if some of the servers that form the group are currently unable to participate in it due to planned maintenance or unplanned issues. As long as the remaining members are a majority of the group they can elect a new primary and continue to function as a group. However, if every member of a replication group leaves the group, and Group Replication is stopped on every member by a `STOP GROUP_REPLICATION` statement or system shutdown, the group now only exists in theory, as a configuration on the members. In that situation, to re-create the group, it must be started by bootstrapping as if it was being started for the first time.

The difference between bootstrapping a group for the first time and doing it for the second or subsequent times is that in the latter situation, the members of a group that was shut down might have different transaction sets from each other, depending on the order in which they were stopped or failed. A member cannot join a group if it has transactions that are not present on the other group members. For Group Replication, this includes both transactions that have been committed and applied, which are in the `gtid_executed` GTID set, and transactions that have been certified but not yet applied, which are in the `group_replication_applier` channel. The exact point at which a transaction is committed depends on the transaction consistency level that is set for the group (see Section 20.5.3, “Transaction Consistency Guarantees”). However, a Group Replication group member never removes a transaction that has been certified, which is a declaration of the member’s intent to commit the transaction.

The replication group must therefore be restarted beginning with the most up to date member, that is, the member that has the most transactions executed and certified. The members with fewer transactions can then join and catch up with the transactions they are missing through distributed recovery. It is not correct to assume that the last known primary member of the group is the most up to date member of the group, because a member that was shut down later than the primary might have
more transactions. You must therefore restart each member to check the transactions, compare all the transaction sets, and identify the most up to date member. This member can then be used to bootstrap the group.

Follow this procedure to restart a replication group safely after every member shuts down.

1. For each group member in turn, in any order:
   a. Connect a client to the group member. If Group Replication is not already stopped, issue a `STOP GROUP_REPLICATION` statement and wait for Group Replication to stop.
   b. Edit the MySQL Server configuration file (typically named `my.cnf` on Linux and Unix systems, or `my.ini` on Windows systems) and set the system variable `group_replication_start_on_boot=OFF`. This setting prevents Group Replication from starting when MySQL Server is started, which is the default.
   If you cannot change that setting on the system, you can just allow the server to attempt to start Group Replication, which will fail because the group has been fully shut down and not yet bootstrapped. If you take that approach, do not set `group_replication_bootstrap_group=ON` on any server at this stage.
   c. Start the MySQL Server instance, and verify that Group Replication has not been started (or has failed to start). Do not start Group Replication at this stage.
   d. Collect the following information from the group member:
      • The contents of the `gtid_executed` GTID set. You can get this by issuing the following statement:
        ```
        mysql> SELECT @@GLOBAL.GTID_EXECUTED
        ```
      • The set of certified transactions on the `group_replication_applier` channel. You can get this by issuing the following statement:
        ```
        mysql> SELECT received_transaction_set FROM performance_schema.replication_connection_status WHERE channel_name="group_replication_applier";
        ```

2. When you have collected the transaction sets from all the group members, compare them to find which member has the biggest transaction set overall, including both the executed transactions (`gtid_executed`) and the certified transactions (on the `group_replication_applier` channel). You can do this manually by looking at the GTIDs, or you can compare the GTID sets using stored functions, as described in Section 19.1.3.8, “Stored Function Examples to Manipulate GTIDs”.

3. Use the member that has the biggest transaction set to bootstrap the group, by connecting a client to the group member and issuing the following statements:

   ```
   mysql> SET GLOBAL group_replication_bootstrap_group=ON;
   mysql> START GROUP_REPLICATION;
   mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
   ```

   It is important not to store the setting `group_replication_bootstrap_group=ON` in the configuration file, otherwise when the server is restarted again, a second group with the same name is set up.

4. To verify that the group now exists with this founder member in it, issue this statement on the member that bootstrapped it:

   ```
   mysql> SELECT * FROM performance_schema.replication_group_members;
   ```

5. Add each of the other members back into the group, in any order, by issuing a `START GROUP_REPLICATION` statement on each of them:
6. To verify that each member has joined the group, issue this statement on any member:

```sql
mysql> SELECT * FROM performance_schema.replication_group_members;
```

7. When the members have rejoined the group, if you edited their configuration files to set `group_replication_start_on_boot=OFF`, you can edit them again to set `ON` (or remove the system variable, since `ON` is the default).

### 20.5.3 Transaction Consistency Guarantees

One of the major implications of a distributed system such as Group Replication is the consistency guarantees that it provides as a group. In other words, the consistency of the global synchronization of transactions distributed across the members of the group. This section describes how Group Replication handles consistency guarantees depending on the events that occur in a group, and how to best configure your group’s consistency guarantees.

#### 20.5.3.1 Understanding Transaction Consistency Guarantees

In terms of distributed consistency guarantees, either in normal or failure repair operations, Group Replication has always been an eventual consistency system. This means that as soon as the incoming traffic slows down or stops, all group members have the same data content. The events that relate to the consistency of a system can be split into control operations, either manual or automatically triggered by failures; and data flow operations.

For Group Replication, the control operations that can be evaluated in terms of consistency are:

- a member joining or leaving, which is covered by Group Replication’s Section 20.5.4, “Distributed Recovery” and write protection.
- network failures, which are covered by the fencing modes.
- in single-primary groups, primary failover, which can also be an operation triggered by `group_replication_set_as_primary()`.

### Consistency Guarantees and Primary Failover

In a single-primary group, in the event of a primary failover when a secondary is promoted to primary, the new primary can either be made available to application traffic immediately, regardless of how large the replication backlog is, or alternatively access to it can be restricted until the backlog has been applied.

With the first approach, the group takes the minimum time possible to secure a stable group membership after a primary failure by electing a new primary and then allowing data access immediately while it is still applying any possible backlog from the old primary. Write consistency is ensured, but reads can temporarily retrieve stale data while the new primary applies the backlog. For example, if client C1 wrote `A=2` WHERE `A=1` on the old primary just before its failure, when client C1 is reconnected to the new primary it could potentially read `A=1` until the new primary applies its backlog and catches up with the state of the old primary before it left the group.

With the second alternative, the system secures a stable group membership after the primary failure and elects a new primary in the same way as the first alternative, but in this case the group then waits until the new primary applies all backlog and only then does it permit data access. This ensures that in a situation as described previously, when client C1 is reconnected to the new primary it reads `A=2`. However, the trade-off is that the time required to failover is then proportional to the size of the backlog, which on a correctly configured group should be small.

You can configure the level of transaction consistency guarantees provided by members during primary failover using the `group_replication_consistency` variable. See Impact of Consistency on Primary Election.
Data Flow Operations

Data flow is relevant to group consistency guarantees due to the reads and writes executed against a group, especially when these operations are distributed across all members. Data flow operations apply to both modes of Group Replication: single-primary and multi-primary, however to make this explanation clearer it is restricted to single-primary mode. The usual way to split incoming read or write transactions across a single-primary group’s members is to route writes to the primary and evenly distribute reads to the secondaries. Since the group should behave as a single entity, it is reasonable to expect that writes on the primary are instantaneously available on the secondaries. Although Group Replication is written using Group Communication System (GCS) protocols that implement the Paxos algorithm, some parts of Group Replication are asynchronous, which implies that data is asynchronously applied to secondaries. This means that a client C2 can write `B=2 WHERE B=1` on the primary, immediately connect to a secondary and read `B=1`. This is because the secondary is still applying backlog, and has not applied the transaction which was applied by the primary.

Transaction Synchronization Points

You configure a group’s consistency guarantee based on the point at which you want to synchronize transactions across the group. To help you understand the concept, this section simplifies the points of synchronizing transactions across a group to be at the time of a read operation or at the time of a write operation. If data is synchronized at the time of a read, the current client session waits until a given point, which is the point in time that all preceding update transactions have been applied, before it can start executing. With this approach, only this session is affected, all other concurrent data operations are not affected.

If data is synchronized at the time of write, the writing session waits until all secondaries have written their data. Group Replication uses a total order on writes, and therefore this implies waiting for this and all preceding writes that are in secondaries’ queues to be applied. Therefore when using this synchronization point, the writing session waits for all secondaries queues to be applied.

Any alternative ensures that in the situation described for client C2 would always read `B=2` even if immediately connected to a secondary. Each alternative has its advantages and disadvantages, which are directly related to your system workload. The following examples describe different types of workloads and advise which point of synchronization is appropriate.

Imagine the following situations:

• you want to load balance your reads without deploying additional restrictions on which server you read from to avoid reading stale data, group writes are much less common than group reads.

• you have a group that has a predominantly read-only data, you want read-write transactions to be applied everywhere once they commit, so that subsequent reads are done on up-to-date data that includes the latest write. This ensures that you do not pay the synchronization cost for every RO transaction, but only on RW ones.

In these cases, you should choose to synchronize on writes.

Imagine the following situations:

• You want to load balance your reads without deploying additional restrictions on which server you read from to avoid reading stale data, group writes are much more common than group reads.

• You want specific transactions in your workload to always read up-to-date data from the group, for example whenever sensitive data is updated (such as credentials for a file or similar data) and you want to enforce that reads retrieve the most up to date value.

In these cases, you should choose to synchronize on reads.

20.5.3.2 Configuring Transaction Consistency Guarantees

Although the Transaction Synchronization Points section explains that conceptually there are two synchronization points from which you can choose: on read or on write, these terms were a
simplification and the terms used in Group Replication are: before and after transaction execution. The consistency level can have a different impact on read-only (RO) and read-write (RW) transactions processed by the group as demonstrated in this section.

- **How to Choose a Consistency Level**
- **Impacts of Consistency Levels**
- **Impact of Consistency on Primary Election**
- **Permitted Queries Under Consistency Rules**

The following list shows the possible consistency levels that you can configure in Group Replication using the `group_replication_consistency` variable, in order of increasing transaction consistency guarantee:

- **EVENTUAL**
  Both RO and RW transactions do not wait for preceding transactions to be applied before executing. This!was the behavior of Group Replication before the `group_replication_consistency` variable was added. A RW transaction does not wait for other members to apply a transaction. This means that a transaction could be externalized on one member before the others. This also means that in the event of a primary failover, the new primary can accept new RO and RW transactions before the previous primary transactions are all applied. RO transactions could result in outdated values, RW transactions could result in a rollback due to conflicts.

- **BEFORE_ON_PRIMARY_FAILOVER**
  New RO or RW transactions with a newly elected primary that is applying backlog from the old primary are held (not applied) until any backlog has been applied. This ensures that when a primary failover happens, intentionally or not, clients always see the latest value on the primary. This guarantees consistency, but means that clients must be able to handle the delay in the event that a backlog is being applied. Usually this delay should be minimal, but it does depend on the size of the backlog.

- **BEFORE**
  A RW transaction waits for all preceding transactions to complete before being applied. A RO transaction waits for all preceding transactions to complete before being executed. This ensures that this transaction reads the latest value by only affecting the latency of the transaction. This reduces the overhead of synchronization on every RW transaction, by ensuring synchronization is used only on RO transactions. This consistency level also includes the consistency guarantees provided by **BEFORE_ON_PRIMARY_FAILOVER**.

- **AFTER**
  A RW transaction waits until its changes have been applied to all of the other members. This value has no effect on RO transactions. This mode ensures that when a transaction is committed on the local member, any subsequent transaction reads the written value or a more recent value on any group member. Use this mode with a group that is used for predominantly RO operations to ensure that applied RW transactions are applied everywhere once they commit. This could be used by your application to ensure that subsequent reads fetch the latest data which includes the latest writes. This reduces the overhead of synchronization on every RO transaction, by ensuring synchronization is used only on RW transactions. This consistency level also includes the consistency guarantees provided by **BEFORE_ON_PRIMARY_FAILOVER**.

- **BEFORE_AND_AFTER**
  A RW transaction waits for 1) all preceding transactions to complete before being applied and 2) until its changes have been applied on other members. A RO transaction waits for all preceding transactions to complete before execution takes place. This consistency level also includes the consistency guarantees provided by **BEFORE_ON_PRIMARY_FAILOVER**.
The BEFORE and BEFORE_AND_AFTER consistency levels can be both used on RO and RW transactions. The AFTER consistency level has no impact on RO transactions, because they do not generate changes.

**How to Choose a Consistency Level**

The different consistency levels provide flexibility to both DBAs, who can use them to set up their infrastructure; and to developers who can use the consistency level that best suits their application's requirements. The following scenarios show how to choose a consistency guarantee level based on how you use your group:

- **Scenario 1** you want to load balance your reads without worrying about stale reads, your group write operations are considerably fewer than your group read operations. In this case, you should choose **AFTER**.

- **Scenario 2** you have a data set that applies a lot of writes and you want to do occasional reads without having to worry about reading stale data. In this case, you should choose **BEFORE**.

- **Scenario 3** you want specific transactions in your workload to always read up-to-date data from the group, so that whenever that sensitive data is updated (such as credentials for a file or similar data) you want to enforce that reads always read the most up to date value. In this case, you should choose **BEFORE**.

- **Scenario 4** you have a group that has predominantly read-only (RO) data, you want your read-write (RW) transactions to be applied everywhere once they commit, so that subsequent reads are done on up-to-date data that includes your latest writes and you do not pay the synchronization on every RO transaction, but only on RW ones. In this case, you should choose **AFTER**.

- **Scenario 5** you have a group that has predominantly read-only data, you want your read-write (RW) transactions to always read up-to-date data from the group and to be applied everywhere once they commit, so that subsequent reads are done on up-to-date data that includes your latest write and you do not pay the synchronization on every read-only (RO) transaction, but only on RW ones. In this case, you should choose **BEFORE_AND_AFTER**.

You have the freedom to choose the scope at which the consistency level is enforced. This is important because consistency levels could have a negative impact on group performance if you set them at a global scope. Therefore you can configure the consistency level of a group by using the group_replication_consistency system variable at different scopes.

To enforce the consistency level on the current session, use the session scope:

```
> SET @@SESSION.group_replication_consistency= 'BEFORE';
```

To enforce the consistency level on all sessions, use the global scope:

```
> SET @@GLOBAL.group_replication_consistency= 'BEFORE';
```

The possibility of setting the consistency level on specific sessions enables you to take advantage of scenarios such as:

- **Scenario 6** A given system handles several instructions that do not require a strong consistency level, but one kind of instruction does require strong consistency: managing access permissions to documents;. In this scenario, the system changes access permissions and it wants to be sure that all clients see the correct permission. You only need to SET @@SESSION.group_replication_consistency= 'AFTER', on those instructions and leave the other instructions to run with EVENTUAL set at the global scope.

- **Scenario 7** On the same system as described in Scenario 6, every day an instruction needs to do some analytical processing, and as such it requires to always read the most up-to-date data. To achieve this, you only need to SET @@SESSION.group_replication_consistency= 'BEFORE' on that specific instruction.
To summarize, you do not need to run all transactions with a specific consistency level, especially if only some transactions actually require it.

Note that all read-write transactions are totally ordered in Group Replication, so even when you set the consistency level to \textit{AFTER} for the current session this transaction waits until its changes are applied on all members, which means waiting for this and all preceding transactions that could be in the secondaries’ queues. In practice, the consistency level \textit{AFTER} waits for everything until and including this transaction.

\textbf{Impacts of Consistency Levels}

Another way to classify the consistency levels is in terms of impact on the group, that is, the repercussions that the consistency levels have on the other members.

The \textit{BEFORE} consistency level, apart from being ordered on the transaction stream, only impacts on the local member. That is, it does not require coordination with the other members and does not have repercussions on their transactions. In other words, \textit{BEFORE} only impacts the transactions on which it is used.

The \textit{AFTER} and \textit{BEFORE_AND_AFTER} consistency levels do have side-effects on concurrent transactions executed on other members. These consistency levels make the other members transactions wait if transactions with the \textit{EVENTUAL} consistency level start while a transaction with \textit{AFTER} or \textit{BEFORE_AND_AFTER} is executing. The other members wait until the \textit{AFTER} transaction is committed on that member, even if the other member’s transactions have the \textit{EVENTUAL} consistency level. In other words, \textit{AFTER} and \textit{BEFORE_AND_AFTER} impact all \texttt{ONLINE} group members.

To illustrate this further, imagine a group with 3 members, M1, M2 and M3. On member M1 a client issues:

\begin{verbatim}
> SET @@SESSION.group_replication_consistency= AFTER;
> BEGIN;
> INSERT INTO t1 VALUES (1);
> COMMIT;
\end{verbatim}

Then, while the above transaction is being applied, on member M2 a client issues:

\begin{verbatim}
> SET SESSION group_replication_consistency= EVENTUAL;
\end{verbatim}

In this situation, even though the second transaction’s consistency level is \textit{EVENTUAL}, because it starts executing while the first transaction is already in the commit phase on M2, the second transaction has to wait for the first transaction to finish the commit and only then can it execute.

You can only use the consistency levels \textit{BEFORE}, \textit{AFTER} and \textit{BEFORE_AND_AFTER} on \texttt{ONLINE} members, attempting to use them on members in other states causes a session error.

Transactions whose consistency level is not \textit{EVENTUAL} hold execution until a timeout, configured by \texttt{wait_timeout} value is reached, which defaults to 8 hours. If the timeout is reached an \texttt{ER_GR_HOLD_WAIT_TIMEOUT} error is thrown.

\textbf{Impact of Consistency on Primary Election}

This section describes how a group's consistency level impacts on a single-primary group that has elected a new primary. Such a group automatically detects failures and adjusts the view of the members that are active, in other words the membership configuration. Furthermore, if a group is deployed in single-primary mode, whenever the group's membership changes there is a check performed to detect if there is still a primary member in the group. If there is none, a new one is selected from the list of secondary members. Typically, this is known as the secondary promotion.

Given the fact that the system detects failures and reconfigures itself automatically, the user may also expect that once the promotion takes place, the new primary is in the exact state, data-wise, as that of the old one. In other words, the user may expect that there is no backlog of replicated transactions to be applied on the new primary once he is able to read from and write to it. In practical terms, the user
may expect that once his application fails-over to the new primary, there would be no chance, even if
temporarily, to read old data or write into old data records.

When flow control is activated and properly tuned on a group, there is only a small chance of
transiently reading stale data from a newly elected primary immediately after the promotion, as
there should not be a backlog, or if there is one it should be small. Moreover, you might have a
proxy or middleware layers that govern application accesses to the primary after a promotion and
enforce the consistency criteria at that level. You can specify the behavior of the new primary once
it is promoted using the group_replication_consistency variable, which controls whether
a newly elected primary blocks both reads and writes until after the backlog is fully applied. If the
group_replication_consistency variable was set to BEFORE_ON_PRIMARY_FAILOVER on a
newly elected primary which has backlog to apply, and transactions are issued against the new primary
while it is still applying the backlog, incoming transactions are blocked until the backlog is fully applied.
Thus, the following anomalies are prevented:

- No stale reads for read-only and read-write transactions. This prevents stale reads from being
  externalized to the application by the new primary.
- No spurious roll backs for read-write transactions, due to write-write conflicts with replicated read-
  write transactions still in the backlog waiting to be applied.
- No read skew on read-write transactions, such as:

  ```
  > BEGIN;
  > SELECT x FROM t1; -- x=1 because x=2 is in the backlog;
  > INSERT x INTO t2;
  > COMMIT;
  ```

  This query should not cause a conflict but writes outdated values.

To summarize, when group_replication_consistency is set to
BEFORE_ON_PRIMARY_FAILOVER you are choosing to prioritize consistency over availability,
because reads and writes are held whenever a new primary is elected. This is the trade-off
you have to consider when configuring your group. It should also be remembered that if flow
control is working correctly, backlog should be minimal. Note that the higher consistency levels
BEFORE, AFTER, and BEFORE_AND_AFTER also include the consistency guarantees provided by
BEFORE_ON_PRIMARY_FAILOVER.

To guarantee that the group provides the same consistency level regardless of which member is
promoted to primary, all members of the group should have BEFORE_ON_PRIMARY_FAILOVER (or a
higher consistency level) persisted to their configuration. For example, on each member issue:

```
> SET PERSIST group_replication_consistency='BEFORE_ON_PRIMARY_FAILOVER';
```

This ensures that the members all behave in the same way, and that the configuration is persisted after
a restart of the member.

A transaction cannot be on-hold forever, and if the time held exceeds wait_timeout it returns an
ER_GR_HOLD_WAIT_TIMEOUT error.

Permitted Queries Under Consistency Rules

Although all writes are held when using BEFORE_ON_PRIMARY_FAILOVER consistency level, not all
reads are blocked to ensure that you can still inspect the server while it is applying backlog after a
promotion took place. This is useful for debugging, monitoring, observability and troubleshooting. Some
queries that do not modify data are allowed, such as the following:

- **SHOW** statements: This is restricted to those that do not depend on data, only on status and
  configuration, as listed below

- **SET** statements

- **DO** statements that do not use tables or loadable functions
Distributed Recovery

• **EMPTY** statements

• **USE** statements

• Using **SELECT** statements against the **performance_schema** and **sys** databases

• Using **SELECT** statements against the **PROCESSLIST** table from the **infoschema** database

• **SELECT** statements that do not use tables or loadable functions

• **STOP GROUP_REPLICATION** statements

• **SHUTDOWN** statements

• **RESET PERSIST** statements

20.5.4 Distributed Recovery

Whenever a member joins or rejoins a replication group, it must catch up with the transactions that were applied by the group members before it joined, or while it was away. This process is called distributed recovery.

The joining member begins by checking the relay log for its **group_replication_applier** channel for any transactions that it already received from the group but did not yet apply. If the joining member was in the group previously, it might find unapplied transactions from before it left, in which case it applies these as a first step. A member that is new to the group does not have anything to apply.

After this, the joining member connects to an online existing member to carry out state transfer. The joining member transfers all the transactions that took place in the group before it joined or while it was away, which are provided by the existing member (called the **donor**). Next, the joining member applies the transactions that took place in the group while this state transfer was in progress. When this process is complete, the joining member has caught up with the remaining servers in the group, and it begins to participate normally in the group.

Group Replication uses a combination of these methods for state transfer during distributed recovery:

• A remote cloning operation using the clone plugin's function. To enable this method of state transfer, you must install the clone plugin on the group members and the joining member. Group Replication automatically configures the required clone plugin settings and manages the remote cloning operation.

• Replicating from a donor's binary log and applying the transactions on the joining member. This method uses a standard asynchronous replication channel named **group_replication_recovery** that is established between the donor and the joining member.

Group Replication automatically selects the best combination of these methods for state transfer after you issue **START GROUP_REPLICATION** on the joining member. To do this, Group Replication checks which existing members are suitable as donors, how many transactions the joining member needs from a donor, and whether any required transactions are no longer present in the binary log files on any group member. If the transaction gap between the joining member and a suitable donor is large, or if some required transactions are not in any donor's binary log files, Group Replication begins distributed recovery with a remote cloning operation. If there is not a large transaction gap, or if the clone plugin is not installed, Group Replication proceeds directly to state transfer from a donor's binary log.
Distributed Recovery

• During a remote cloning operation, the existing data on the joining member is removed, and replaced with a copy of the donor's data. When the remote cloning operation is complete and the joining member has restarted, state transfer from a donor's binary log is carried out to get the transactions that the group applied while the remote cloning operation was in progress.

• During state transfer from a donor's binary log, the joining member replicates and applies the required transactions from the donor's binary log, applying the transactions as they are received, up to the point where the binary log records that the joining member joined the group (a view change event). While this is in progress, the joining member buffers the new transactions that the group applies. When state transfer from the binary log is complete, the joining member applies the buffered transactions.

When the joining member is up to date with all the group's transactions, it is declared online and can participate in the group as a normal member, and distributed recovery is complete.

Tip
State transfer from the binary log is Group Replication's base mechanism for distributed recovery, and if the donors and joining members in your replication group are not set up to support cloning, this is the only available option. As state transfer from the binary log is based on classic asynchronous replication, it might take a very long time if the server joining the group does not have the group's data at all, or has data taken from a very old backup image. In this situation, it is therefore recommended that before adding a server to the group, you should set it up with the group's data by transferring a fairly recent snapshot of a server already in the group. This minimizes the time taken for distributed recovery, and reduces the impact on donor servers, since they have to retain and transfer fewer binary log files.

20.5.4.1 Connections for Distributed Recovery

When a joining member connects to an online existing member for state transfer during distributed recovery, the joining member acts as a client on the connection and the existing member acts as a server. When state transfer from the donor's binary log is in progress over this connection (using the asynchronous replication channel group_replication_recovery), the joining member acts as the replica and the existing member acts as the source. When a remote cloning operation is in progress over this connection, the joining member acts as a recipient and the existing member acts as a donor. Configuration settings that apply to those roles outside the Group Replication context can apply for Group Replication also, unless they are overridden by a Group Replication-specific configuration setting or behavior.

The connection that an existing member offers to a joining member for distributed recovery is not the same connection that is used by Group Replication for communication between online members of the group.

• The connection used by the group communication engine for Group Replication (XCom, a Paxos variant) for TCP communication between remote XCom instances is specified by the group_replication_local_address system variable. This connection is used for TCP/IP messages between online members. Communication with the local instance is over an input channel using shared memory.

• For distributed recovery, by default, group members offer their standard SQL client connection to joining members, as specified by MySQL Server's hostname and port system variables. If an alternative port number is specified by the report_port system variable, that one is used instead.

• Group members may instead advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members, allowing you to control distributed recovery traffic separately from connections by regular client users of the member. You specify this list using the group_replication_advertise_recovery_endpoints system variable, and the member transmits their list of distributed recovery endpoints to the group when they join the group. The
default is that the member continues to offer the standard SQL client connection as in earlier releases.

Important

Distributed recovery can fail if a joining member cannot correctly identify the other members using the host name as defined by MySQL Server's `hostname` system variable. It is recommended that operating systems running MySQL have a properly configured unique host name, either using DNS or local settings. The host name that the server is using for SQL client connections can be verified in the `Member_host` column of the Performance Schema table `replication_group_members`. If multiple group members externalize a default host name set by the operating system, there is a chance of the joining member not resolving it to the correct member address and not being able to connect for distributed recovery. In this situation you can use MySQL Server’s `report_host` system variable to configure a unique host name to be externalized by each of the servers.

The steps for a joining member to establish a connection for distributed recovery are as follows:

1. When the member joins the group, it connects with one of the seed members included in the list in its `group_replication_group_seeds` system variable, initially using the `group_replication_local_address` connection as specified in that list. The seed members might be a subset of the group.

2. Over this connection, the seed member uses Group Replication's membership service to provide the joining member with a list of all the members that are online in the group, in the form of a view. The membership information includes the details of the distributed recovery endpoints or standard SQL client connection offered by each member for distributed recovery.

3. The joining member selects a suitable group member from this list to be its donor for distributed recovery, following the behaviors described in Section 20.5.4.4, “Fault Tolerance for Distributed Recovery”.

4. The joining member then attempts to connect to the donor using the donor's advertised distributed recovery endpoints, trying each in turn in the order they are specified in the list. If the donor provides no endpoints, the joining member attempts to connect using the donor's standard SQL client connection. The SSL requirements for the connection are as specified by the `group_replication_recovery_ssl_*` options described in SSL and Authentication for Distributed Recovery.

5. If the joining member is not able to connect to the selected donor, it retries with other suitable donors, following the behaviors described in Section 20.5.4.4, “Fault Tolerance for Distributed Recovery”. Note that if the joining member exhausts the list of advertised endpoints without making a connection, it does not fall back to the donor's standard SQL client connection, but switches to another donor.

6. When the joining member establishes a distributed recovery connection with a donor, it uses that connection for state transfer as described in Section 20.5.4, “Distributed Recovery”. The host and port for the connection that is used are shown in the joining member's log. Note that if a remote cloning operation is used, when the joining member has restarted at the end of the operation, it establishes a connection with a new donor for state transfer from the binary log. This might be a connection to a different member from the original donor used for the remote cloning operation, or it might be a different connection to the original donor. In any case, the distributed recovery process continues in the same way as it would have with the original donor.

Selecting addresses for distributed recovery endpoints

IP addresses supplied by the `group_replication_advertise_recovery_endpoints` system variable as distributed recovery endpoints do not have to be configured for MySQL Server (that
Distributed Recovery

is, they do not have to be specified by the `admin_address` system variable or in the list for the `bind_address` system variable). They do have to be assigned to the server. Any host names used must resolve to a local IP address. IPv4 and IPv6 addresses can be used.

The ports supplied for the distributed recovery endpoints do have to be configured for MySQL Server, so they must be specified by the `port`, `report_port`, or `admin_port` system variable. The server must listen for TCP/IP connections on these ports. If you specify the `admin_port`, the replication user for distributed recovery needs the `SERVICE_CONNECTION_ADMIN` privilege to connect. Selecting the `admin_port` keeps distributed recovery connections separate from regular MySQL client connections.

Joining members try each of the endpoints in turn in the order they are specified on the list. If `group_replication_advertise_recovery_endpoints` is set to `DEFAULT` rather than a list of endpoints, the standard SQL client connection is offered. Note that the standard SQL client connection is not automatically included on a list of distributed recovery endpoints, and is not offered as a fallback if the donor's list of endpoints is exhausted without a connection. If you want to offer the standard SQL client connection as one of a number of distributed recovery endpoints, you must include it explicitly in the list specified by `group_replication_advertise_recovery_endpoints`. You can put it in the last place so that it acts as a last resort for connection.

A group member's distributed recovery endpoints (or standard SQL client connection if endpoints are not provided) do not need to be added to the Group Replication allowlist specified by the `group_replication_ip_allowlist` system variable. The allowlist is only for the address specified by `group_replication_local_address` for each member. A joining member must have its initial connection to the group permitted by the allowlist in order to retrieve the address or addresses for distributed recovery.

The distributed recovery endpoints that you list are validated when the system variable is set and when a `START GROUP_REPLICATION` statement has been issued. If the list cannot be parsed correctly, or if any of the endpoints cannot be accessed on the host because the server is not listening on them, Group Replication logs an error and does not start.

**Compression for Distributed Recovery**

You can optionally configure compression for distributed recovery by the method of state transfer from a donor's binary log. Compression can benefit distributed recovery where network bandwidth is limited and the donor has to transfer many transactions to the joining member. The `group_replication_recovery_compression_algorithms` and `group_replication_recovery_zstd_compression_level` system variables configure permitted compression algorithms, and the `zstd` compression level, used when carrying out state transfer from a donor's binary log. For more information, see Section 6.2.8, “Connection Compression Control”.

Note that these compression settings do not apply for remote cloning operations. When a remote cloning operation is used for distributed recovery, the clone plugin's `clone_enable_compression` setting applies.

**Replication User for Distributed Recovery**

Distributed recovery requires a replication user that has the correct permissions so that Group Replication can establish direct member-to-member replication channels. The replication user must also have the correct permissions to act as the clone user on the donor for a remote cloning operation. The same replication user must be used for distributed recovery on every group member. For instructions to set up this replication user, see Section 20.2.1.3, “User Credentials For Distributed Recovery”. For instructions to secure the replication user credentials, see Section 20.6.3.1, “Secure User Credentials for Distributed Recovery”.

**SSL and Authentication for Distributed Recovery**

SSL for distributed recovery is configured separately from SSL for normal group communications, which is determined by the server's SSL settings and the `group_replication_ssl_mode` system...
Distributed Recovery

variable. For distributed recovery connections, dedicated Group Replication distributed recovery SSL system variables are available to configure the use of certificates and ciphers specifically for distributed recovery.

By default, SSL is not used for distributed recovery connections. To activate it, set `group_replication_recovery_use_ssl=ON`, and configure the Group Replication distributed recovery SSL system variables as described in Section 20.6.3, “Securing Distributed Recovery Connections”. You need a replication user that is set up to use SSL.

When distributed recovery is configured to use SSL, Group Replication applies this setting for remote cloning operations, as well as for state transfer from a donor’s binary log. Group Replication automatically configures the settings for the clone SSL options (`clone_ssl_ca`, `clone_ssl_cert`, and `clone_ssl_key`) to match your settings for the corresponding Group Replication distributed recovery options (`group_replication_recovery_ssl_ca`, `group_replication_recovery_ssl_cert`, and `group_replication_recovery_ssl_key`).

If you are not using SSL for distributed recovery (so `group_replication_recovery_use_ssl` is set to `OFF`), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (the default) or the `sha256_password` plugin (deprecated), RSA key pairs are used for password exchange. In this case, either use the `group_replication_recovery_public_key_path` system variable to specify the RSA public key file, or use the `group_replication_recovery_get_public_key` system variable to request the public key from the source, as described in Replication User With The Caching SHA-2 Authentication Plugin.

20.5.4.2 Cloning for Distributed Recovery

If you want to use remote cloning operations for distributed recovery in a group, you must set up existing members and joining members beforehand to support this function. If you do not want to use this function in a group, do not set it up, in which case Group Replication only uses state transfer from the binary log.

To use cloning, at least one existing group member and the joining member must be set up beforehand to support remote cloning operations. As a minimum, you must install the clone plugin on the donor and joining member, grant the `BACKUP_ADMIN` permission to the replication user for distributed recovery, and set the `group_replication_clone_threshold` system variable to an appropriate level.

To ensure the maximum availability of donors, it is advisable to set up all current and future group members to support remote cloning operations.

Be aware that a remote cloning operation removes user-created tablespaces and data from the joining member before transferring the data from the donor. If the operation is stopped while in progress, the joining member might be left with partial data or no data. This can be repaired by retrying the remote cloning operation, which Group Replication does automatically.

Prerequisites for Cloning

For full instructions to set up and configure the clone plugin, see Section 7.6.7, “The Clone Plugin”. Detailed prerequisites for a remote cloning operation are covered in Section 7.6.7.3, “Cloning Remote Data”. For Group Replication, note the following key points and differences:

- The donor (an existing group member) and the recipient (the joining member) must have the clone plugin installed and active. For instructions to do this, see Section 7.6.7.1, “Installing the Clone Plugin”.

- The donor and the recipient must run on the same operating system, and must be on the same MySQL Server version series. Cloning is therefore not suitable for groups where members run different minor MySQL Server versions, such as MySQL 8.0 and 8.4.

- The donor and the recipient must have the Group Replication plugin installed and active, and any other plugins that are active on the donor (such as a keyring plugin) must also be active on the recipient.
Distributed Recovery

• If distributed recovery is configured to use SSL (\texttt{group\_replication\_recovery\_use\_ssl=ON}), Group Replication applies this setting for remote cloning operations. Group Replication automatically configures the settings for the clone SSL options (\texttt{clone\_ssl\_ca}, \texttt{clone\_ssl\_cert}, and \texttt{clone\_ssl\_key}) to match your settings for the corresponding Group Replication distributed recovery options (\texttt{group\_replication\_recovery\_ssl\_ca}, \texttt{group\_replication\_recovery\_ssl\_cert}, and \texttt{group\_replication\_recovery\_ssl\_key}).

• You do not need to set up a list of valid donors in the \texttt{clone\_valid\_donor\_list} system variable for the purpose of joining a replication group. Group Replication configures this setting automatically for you after it selects a donor from the existing group members. Note that remote cloning operations use the server's SQL protocol hostname and port.

• The clone plugin has a number of system variables to manage the network load and performance impact of the remote cloning operation. Group Replication does not configure these settings, so you can review them and set them if you want to, or allow them to default. Note that when a remote cloning operation is used for distributed recovery, the clone plugin's \texttt{clone\_enable\_compression} setting applies to the operation, rather than the Group Replication compression setting.

• To invoke the remote cloning operation on the recipient, Group Replication uses the internal \texttt{mysql\_session} user, which already has the \texttt{CLONE\_ADMIN} privilege, so you do not need to set this up.

• As the clone user on the donor for the remote cloning operation, Group Replication uses the replication user that you set up for distributed recovery (which is covered in Section 20.2.1.3, "User Credentials For Distributed Recovery"). You must therefore give the \texttt{BACKUP\_ADMIN} privilege to this replication user on all group members that support cloning. Also give the privilege to the replication user on joining members when you are configuring them for Group Replication, because they can act as donors after they join the group. The same replication user is used for distributed recovery on every group member. To give this privilege to the replication user on existing members, you can issue this statement on each group member individually with binary logging disabled, or on one group member with binary logging enabled:

\begin{verbatim}
GRANT BACKUP_ADMIN ON *.* TO rpl_user@'\%';
\end{verbatim}

• If you use \texttt{START GROUP\_REPLICATION} to specify the replication user credentials on a server that previously supplied the user credentials using \texttt{CHANGE REPLICATION SOURCE TO}, ensure that you remove the user credentials from the replication metadata repositories before any remote cloning operations take place. Also ensure that \texttt{group\_replication\_start\_on\_boot=OFF} is set on the joining member. For instructions, see Section 20.6.3, "Securing Distributed Recovery Connections". If you do not unset the user credentials, they are transferred to the joining member during remote cloning operations. The \texttt{group\_replication\_recovery} channel could then be inadvertently started with the stored credentials, on either the original member or members that were cloned from it. An automatic start of Group Replication on server boot (including after a remote cloning operation) would use the stored user credentials, and they would also be used if an operator did not specify the distributed recovery credentials on a \texttt{START GROUP\_REPLICATION} command.

Threshold for Cloning

When group members have been set up to support cloning, the \texttt{group\_replication\_clone\_threshold} system variable specifies a threshold, expressed as a number of transactions, for the use of a remote cloning operation in distributed recovery. If the gap between the transactions on the donor and the transactions on the joining member is larger than this number, a remote cloning operation is used for state transfer to the joining member when this is technically possible. Group Replication calculates whether the threshold has been exceeded based on the \texttt{gtid\_executed} sets of the existing group members. Using a remote cloning operation in the event of a large transaction gap lets you add new members to the group without transferring the group's data to the server manually beforehand, and also enables a member that is very out of date to catch up more efficiently.

The default setting for the \texttt{group\_replication\_clone\_threshold} Group Replication system variable is extremely high (the maximum permitted sequence number for a transaction in a GTID), so it
effectively deactivates cloning wherever state transfer from the binary log is possible. To enable Group Replication to select a remote cloning operation for state transfer where this is more appropriate, set the system variable to specify a number of transactions as the transaction gap above which you want cloning to take place.

**Warning**

Do not use a low setting for `group_replication_clone_threshold` in an active group. If a number of transactions above the threshold takes place in the group while the remote cloning operation is in progress, the joining member triggers a remote cloning operation again after restarting, and could continue this indefinitely. To avoid this situation, ensure that you set the threshold to a number higher than the number of transactions that you would expect to occur in the group during the time taken for the remote cloning operation.

Group Replication attempts to execute a remote cloning operation regardless of your threshold when state transfer from a donor's binary log is impossible, for example because the transactions needed by the joining member are not available in the binary log on any existing group member. Group Replication identifies this based on the `gtid_purged` sets of the existing group members. You cannot use the `group_replication_clone_threshold` system variable to deactivate cloning when the required transactions are not available in any member's binary log files, because in that situation cloning is the only alternative to transferring data to the joining member manually.

**Cloning Operations**

When group members and joining members are set up for cloning, Group Replication manages remote cloning operations for you. A remote cloning operation might take some time to complete, depending on the size of the data. See Section 7.6.7.10, “Monitoring Cloning Operations” for information on monitoring the process.

**Note**

When state transfer is complete, Group Replication restarts the joining member to complete the process. If `group_replication_start_on_boot=OFF` is set on the joining member, for example because you specify the replication user credentials on the `START GROUP_REPLICATION` statement, you must issue `START GROUP_REPLICATION` manually again following this restart. If `group_replication_start_on_boot=ON` and other settings required to start Group Replication were set in a configuration file or using a `SET PERSIST` statement, you do not need to intervene and the process continues automatically to bring the joining member online.

A remote cloning operation clones settings that are persisted in tables from the donor to the recipient, as well as the data. Group Replication manages the settings that relate specifically to Group Replication channels. Group Replication member settings that are persisted in configuration files, such as the group replication local address, are not cloned and are not changed on the joining member. Group Replication also preserves the channel settings that relate to the use of SSL, so these are unique to the individual member.

If the replication user credentials used by the donor for the `group_replication_recovery` replication channel have been stored in the replication metadata repositories using a `CHANGE REPLICA TION SOURCE TO` statement, they are transferred to and used by the joining member after cloning, and they must be valid there. With stored credentials, all group members that received state transfer by a remote cloning operation therefore automatically receive the replication user and password for distributed recovery. If you specify the replication user credentials on the `START GROUP_REPLICATION` statement, these are used to start the remote cloning operation, but they are not transferred to and used by the joining member after cloning. If you do not want the credentials transferred to new joiners and recorded there, ensure that you unset them before remote cloning operations take place, as described in Section 20.6.3, “Securing Distributed Recovery Connections”, and use `START GROUP_REPLICATION` to supply them instead.
If a PRIVILEGE_CHECKS_USER account has been used to help secure the replication appliers (see Section 19.3.3.2, “Privilege Checks For Group Replication Channels”), the PRIVILEGE_CHECKS_USER account and related settings from the donor are cloned to the joining member. If the joining member is set to start Group Replication on boot, it automatically uses the account for privilege checks on the appropriate replication channels.

**Cloning for Other Purposes**

Group Replication initiates and manages cloning operations for distributed recovery. Group members that have been set up to support cloning may also participate in cloning operations that a user initiates manually. For example, you might want to create a new server instance by cloning from a group member as the donor, but you do not want the new server instance to join the group immediately, or maybe not ever.

In all releases that support cloning, you can initiate a cloning operation manually involving a group member on which Group Replication is stopped. Note that because cloning requires that the active plugins on a donor and recipient must match, the Group Replication plugin must be installed and active on the other server instance, even if you do not intend that server instance to join a group. You can install the plugin by issuing this statement:

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

You can initiate a cloning operation manually if the operation involves a group member on which Group Replication is running, provided that the cloning operation does not remove and replace the data on the recipient. The statement to initiate the cloning operation must therefore include the **DATA DIRECTORY** clause if Group Replication is running.

**20.5.4.3 Configuring Distributed Recovery**

Several aspects of Group Replication’s distributed recovery process can be configured to suit your system.

**Number of Connection Attempts**

For state transfer from the binary log, Group Replication limits the number of attempts a joining member makes when trying to connect to a donor from the pool of donors. If the connection retry limit is reached without a successful connection, the distributed recovery procedure terminates with an error. Note that this limit specifies the total number of attempts that the joining member makes to connect to a donor. For example, if 2 group members are suitable donors, and the connection retry limit is set to 4, the joining member makes 2 attempts to connect to each of the donors before reaching the limit.

The default connection retry limit is 10. You can configure this setting using the `group_replication_recovery_retry_count` system variable. The following command sets the maximum number of attempts to connect to a donor to 5:

```
mysql> SET GLOBAL group_replication_recovery_retry_count= 5;
```

For remote cloning operations, this limit does not apply. Group Replication makes only one connection attempt to each suitable donor for cloning, before starting to attempt state transfer from the binary log.

**Sleep Interval for Connection Attempts**

For state transfer from the binary log, the `group_replication_recovery_reconnect_interval` system variable defines how much time the distributed recovery process should sleep between donor connection attempts. Note that distributed recovery does not sleep after every donor connection attempt. As the joining member is connecting to different servers and not to the same one repeatedly, it can assume that the problem that affects server A does not affect server B. Distributed recovery therefore suspends only when it has gone through all the possible donors. Once the server joining the group has made one attempt to connect to each of the suitable donors.
in the group, the distributed recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` system variable. For example, if 2 group members are suitable donors, and the connection retry limit is set to 4, the joining member makes one attempt to connect to each of the donors, then sleeps for the connection retry interval, then makes one further attempt to connect to each of the donors before reaching the limit.

The default connection retry interval is 60 seconds, and you can change this value dynamically. The following command sets the distributed recovery donor connection retry interval to 120 seconds:

```
mysql> SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

For remote cloning operations, this interval does not apply. Group Replication makes only one connection attempt to each suitable donor for cloning, before starting to attempt state transfer from the binary log.

### Marking the Joining Member Online

When distributed recovery has successfully completed state transfer from the donor to the joining member, the joining member can be marked as online in the group and ready to participate. This is done after the new member has received and applied all the transactions that it missed prior to joining the group.

### 20.5.4.4 Fault Tolerance for Distributed Recovery

Group Replication's distributed recovery process has a number of built-in measures to ensure fault tolerance in the event of any problems during the process.

The donor for distributed recovery is selected randomly from the existing list of suitable online group members in the current view. Selecting a random donor means that there is a good chance that the same server is not selected more than once when multiple members enter the group. For state transfer from the binary log, the joinery selects only a donor that is running a lower or equal patch version of MySQL Server compared to itself. For earlier releases, all of the online members are allowed to be a donor. For a remote cloning operation, the joiner only selects a donor that is running the same patch version as itself. Note that when the joining member has restarted at the end of the operation, it establishes a connection with a new donor for state transfer from the binary log, which might be a different member from the original donor used for the remote cloning operation.

In the following situations, Group Replication detects an error in distributed recovery, automatically switches over to a new donor, and retries the state transfer:

- **Connection error** - There is an authentication issue or another problem with making the connection to a candidate donor.

- **Replication errors** - One of the replication threads (the receiver or applier threads) being used for state transfer from the binary log fails. Because this method of state transfer uses the existing MySQL replication framework, it is possible that some transient errors could cause errors in the receiver or applier threads.

- **Remote cloning operation errors** - A remote cloning operation fails or is stopped before it completes.

- **Donor leaves the group** - The donor leaves the group, or Group Replication is stopped on the donor, while state transfer is in progress.

The Performance Schema table `replication_applier_status_by_worker` displays the error that caused the last retry. In these situations, the new connection following the error is attempted with a new candidate donor. Selecting a different donor in the event of an error means that there is a chance the new candidate donor does not have the same error. If the clone plugin is installed, Group Replication attempts a remote cloning operation with each of the suitable online clone-supporting donors first. If all those attempts fail, Group Replication attempts state transfer from the binary log with all the suitable donors in turn, if that is possible.
Warning

For a remote cloning operation, user-created tablespaces and data on the recipient (the joining member) are dropped before the remote cloning operation begins to transfer the data from the donor. If the remote cloning operation starts but does not complete, the joining member might be left with a partial set of its original data files, or with no user data. Data transferred by the donor is removed from the recipient if the cloning operation is stopped before the data is fully cloned. This situation can be repaired by retrying the cloning operation, which Group Replication does automatically.

In the following situations, the distributed recovery process cannot be completed, and the joining member leaves the group:

- **Purged transactions** - Transactions that are required by the joining member are not present in any online group member’s binary log files, and the data cannot be obtained by a remote cloning operation (because the clone plugin is not installed, or because cloning was attempted with all possible donors but failed). The joining member is therefore unable to catch up with the group.

- **Extra transactions** - The joining member already contains some transactions that are not present in the group. If a remote cloning operation was carried out, these transactions would be deleted and lost, because the data directory on the joining member is erased. If state transfer from a donor’s binary log was carried out, these transactions could conflict with the group’s transactions. For advice on dealing with this situation, see Extra Transactions.

- **Connection retry limit reached** - The joining member has made all the connection attempts allowed by the connection retry limit. You can configure this using the `group_replication_recovery_retry_count` system variable (see Section 20.5.4.3, “Configuring Distributed Recovery”).

- **No more donors** - The joining member has unsuccessfully attempted a remote cloning operation with each of the online clone-supporting donors in turn (if the clone plugin is installed), then has unsuccessfully attempted state transfer from the binary log with each of the suitable online donors in turn, if possible.

- **Joining member leaves the group** - The joining member leaves the group or Group Replication is stopped on the joining member while state transfer is in progress.

If the joining member left the group unintentionally, so in any situation listed above except the last, it proceeds to take the action specified by the `group_replication_exit_state_action` system variable.

### 20.5.4.5 How Distributed Recovery Works

When Group Replication’s distributed recovery process is carrying out state transfer from the binary log, to synchronize the joining member with the donor up to a specific point in time, the joining member and donor make use of GTIDs (see Section 19.1.3, “Replication with Global Transaction Identifiers”). However, GTIDs only provide a means to realize which transactions the joining member is missing. They do not help marking a specific point in time to which the server joining the group must catch up, nor do they convey certification information. This is the job of binary log view markers, which mark view changes in the binary log stream, and also contain additional metadata information, supplying the joining member with missing certification-related data.

This topic explains the role of view changes and the view change identifier, and the steps to carry out state transfer from the binary log.

### View and View Changes

A view corresponds to a group of members participating actively in the current configuration, in other words at a specific point in time. They are functioning correctly and online in the group.
A view change occurs when a modification to the group configuration happens, such as a member joining or leaving. Any group membership change results in an independent view change communicated to all members at the same logical point in time.

A view identifier uniquely identifies a view. It is generated whenever a view change happens.

At the group communication layer, view changes with their associated view identifiers mark boundaries between the data exchanged before and after a member joins. This concept is implemented through a binary log event: the "view change log event" (VCLE). The view identifier is recorded to demarcate transactions transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: a randomly generated part, and a monotonically increasing integer. The randomly generated part is generated when the group is created, and remains unchanged while there is at least one member in the group. The integer is incremented every time a view change happens. Using these two different parts enables the view identifier to identify incremental group changes caused by members joining or leaving, and also to identify the situation where all members leave the group in a full group shutdown, so no information remains of what view the group was in. Randomly generating part of the identifier when the group is started from the beginning ensures that the data markers in the binary log remain unique, and an identical identifier is not reused after a full group shutdown, as this would cause issues with distributed recovery in the future.

Begin: Stable Group

All servers are online and processing incoming transactions from the group. Some servers may be a little behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed and replicated database.

Figure 20.8 Stable Group
View Change: a Member Joins

Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the joining member selects a suitable donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a view change event to the binary log.

Figure 20.9 A Member Joins

State Transfer: Catching Up

If group members and the joining member are set up with the clone plugin (see Section 20.5.4.2, “Cloning for Distributed Recovery”), and the difference in transactions between the joining member and the group exceeds the threshold set for a remote cloning operation (group_replication_clone_threshold), Group Replication begins distributed recovery with a remote cloning operation. A remote cloning operation is also carried out if required transactions are no longer present in any group member’s binary log files. During a remote cloning operation, the existing data on the joining member is removed, and replaced with a copy of the donor’s data. When the remote cloning operation is complete and the joining member has restarted, state transfer from a donor’s binary log is carried out to get the transactions that the group applied while the remote cloning operation was in progress. If there is not a large transaction gap, or if the clone plugin is not installed, Group Replication proceeds directly to state transfer from a donor’s binary log.
For state transfer from a donor's binary log, a connection is established between the joining member and the donor and state transfer begins. This interaction with the donor continues until the server joining the group's applier thread processes the view change log event that corresponds to the view change triggered when the server joining the group came into the group. In other words, the server joining the group replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

**Figure 20.10 State Transfer: Catching Up**

As view identifiers are transmitted to all members in the group at the same logical time, the server joining the group knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view identifier clearly marks which data belongs to each group view.

While the server joining the group is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.
When the server joining the group recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the server joining the group entered the group, in other words the last view change. Without it, the server joining the group would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the server joining the group does not block any other server in the group while it is catching up. Therefore the number of transactions the server joining the group is behind when it moves to this stage can, for this reason, vary and thus increase or decrease according to the workload.
Support For IPv6 And For Mixed IPv6 And IPv4 Groups

When the server joining the group reaches zero queued transactions and its stored data is equal to the other members, its public state changes to online.

Figure 20.12 Instance Online

20.5.5 Support For IPv6 And For Mixed IPv6 And IPv4 Groups

Group Replication group members can use IPv6 addresses as an alternative to IPv4 addresses for communications within the group. To use IPv6 addresses, the operating system on the server host and the MySQL Server instance must both be configured to support IPv6. For instructions to set up IPv6 support for a server instance, see Section 7.1.13, “IPv6 Support”.

IPv6 addresses, or host names that resolve to them, can be specified as the network address that the member provides in the `group_replication_local_address` option for connections from other members. When specified with a port number, an IPv6 address must be specified in square brackets, for example:

```
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

The network address or host name specified in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. The address or host name specified as the Group Replication local address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. For the purpose of IP address permissions for Group Replication (see Section 20.6.4, “Group Replication IP Address Permissions”), the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_allowlist` system variable on the other servers in the replication group.
A replication group can contain a combination of members that present an IPv6 address as their Group Replication local address, and members that present an IPv4 address. When a server joins such a mixed group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 Group Replication local address, or the reverse, you must also set up and permit an alternative address for the joining member for the required protocol (or a host name that resolves to an address for that protocol). If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. The alternative address or host name only needs to be added to the `group_replication_ip_allowlist` system variable on the other servers in the replication group, not to the `group_replication_local_address` value for the joining member (which can only contain a single address).

For example, server A is a seed member for a group, and has the following configuration settings for Group Replication, so that it is advertising an IPv6 address in the `group_replication_group_seeds` option:

```sql
group_replication_bootstrap_group=on
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B is a joining member for the group, and has the following configuration settings for Group Replication, so that it has an IPv4 Group Replication local address:

```sql
group_replication_bootstrap_group=off
group_replication_local_address= "203.0.113.21:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B also has an alternative IPv6 address `2001:db8:8b0:40:3d9c:cc43:e006:19e8`. For Server B to join the group successfully, both its IPv4 Group Replication local address, and its alternative IPv6 address, must be listed in Server A's allowlist, as in the following example:

```sql
group_replication_ip_allowlist=
"203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,
2001:db8:8b0:40:3d9c:cc43:e006:19e8"
```

As a best practice for Group Replication IP address permissions, Server B (and all other group members) should have the same allowlist as Server A, unless security requirements demand otherwise.

If any or all members of a replication group are using an older MySQL Server version that does not support the use of IPv6 addresses for Group Replication, a member cannot participate in the group using an IPv6 address (or a host name that resolves to one) as its Group Replication local address. This applies both in the case where at least one existing member uses an IPv6 address and a new member that does not support this attempts to join, and in the case where a new member attempts to join using an IPv6 address but the group includes at least one member that does not support this. In each situation, the new member cannot join. To make a joining member present an IPv4 address for group communications, you can either change the value of `group_replication_local_address` to an IPv4 address, or configure your DNS to resolve the joining member's existing host name to an IPv4 address. After you have upgraded every group member to a MySQL Server version that supports IPv6 for Group Replication, you can change the `group_replication_local_address` value for each member to an IPv6 address, or configure your DNS to present an IPv6 address. Changing the value of `group_replication_local_address` takes effect only when you stop and restart Group Replication.

IPv6 addresses can also be used as distributed recovery endpoints, which can be specified using the `group_replication_advertise_recovery_endpoints` system variable. The same rules apply to addresses used in this list. See Section 20.5.4.1, “Connections for Distributed Recovery”.

---

20.5.6 Using MySQL Enterprise Backup with Group Replication
MySQL Enterprise Backup is a commercially-licensed backup utility for MySQL Server, available with MySQL Enterprise Edition. This section explains how to back up and subsequently restore a Group Replication member using MySQL Enterprise Backup. The same technique can be used to quickly add a new member to a group.

Back up a Group Replication Member Using MySQL Enterprise Backup

Backing up a Group Replication member is similar to backing up a stand-alone MySQL instance. The following instructions assume that you are already familiar with how to use MySQL Enterprise Backup to perform a backup; if that is not the case, please review Backing Up a Database Server. Also note the requirements described in Grant MySQL Privileges to Backup Administrator and Using MySQL Enterprise Backup with Group Replication.

Consider the following group with three members, s1, s2, and s3, running on hosts with the same names:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-------------+-------------+--------------+
<table>
<thead>
<tr>
<th>member_host</th>
<th>member_port</th>
<th>member_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>s1</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>s2</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>s3</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
</tbody>
</table>
+-------------+-------------+--------------+
```

Using MySQL Enterprise Backup, create a backup of s2 by issuing on its host, for example, the following command:

```bash
s2> mysqlbackup --defaults-file=/etc/my.cnf --backup-image=/backups/my.mbi_`date +%d%m_%H%M` --backup-dir=/backups/backup_`date +%d%m_%H%M` --user=root -p --host=127.0.0.1 backup-to-image
```

Restoring a Failed Member

Assume one of the members (s3 in the following example) is irreconcilably corrupted. The most recent backup of group member s2 can be used to restore s3. Here are the steps for performing the restore:

1. **Copy the backup of s2 onto the host for s3.** The exact way to copy the backup depends on the operating system and tools available to you. In this example, we assume the hosts are both Linux servers and use SCP to copy the files between them:

   ```bash
   s2/backups> scp my.mbi_2206_1429 s3:/backups
   ```

2. **Restore the backup.** Connect to the target host (the host for s3 in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

   a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

   ```bash
   s3> systemctl stop mysqld
   ```

   b. Preserve the two configuration files in the corrupted server's data directory, auto.cnf and mysqld-auto.cnf (if it exists), by copying them to a safe location outside of the data directory. This is for preserving the server's UUID and Section 7.1.9.3, "Persisted System Variables" (if used), which are needed in the steps below.

   ```bash
   s3> rm -rf /var/lib/mysql/*
   ```

   If the system variables innodb_data_home_dir, innodb_log_group_home_dir, and innodb_undo_directory point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

   c. Delete all contents in the data directory of s3. For example:

   ```bash
   s3> rm -rf /var/lib/mysql/*
   ```

   d. Restore backup of s2 onto the host for s3:
Using MySQL Enterprise Backup with Group Replication

```
s3> mysqlbackup --defaults-file=/etc/my.cnf /etc/my.cnf 
--datadir=/var/lib/mysql 
--backup-image=/backups/my.mbi_2206_1429 
--backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

**Note**

The command above assumes that the binary logs and relay logs on `s2` and `s3` have the same base name and are at the same location on the two servers. If these conditions are not met, you should use the `--log-bin` and `--relay-log` options to restore the binary log and relay log to their original file paths on `s3`. For example, if you know that on `s3` the binary log's base name is `s3-bin` and the relay-log's base name is `s3-relay-bin`, your restore command should look like:

```
mysqlbackup --defaults-file=/etc/my.cnf 
--datadir=/var/lib/mysql 
--backup-image=/backups/my.mbi_2206_1429 
--log-bin=s3-bin --relay-log=s3-relay-bin 
--backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

Being able to restore the binary log and relay log to the right file paths makes the restore process easier; if that is impossible for some reason, see Rebuild the Failed Member to Rejoin as a New Member.

3. **Restore the auto.cnf file for s3.** To rejoin the replication group, the restored member must have the same `server_uuid` it used to join the group before. Supply the old server UUID by copying the `auto.cnf` file preserved in step 2 above into the data directory of the restored member.

**Note**

If you cannot supply the failed member’s original `server_uuid` to the restored member by restoring its old `auto.cnf` file, you must let the restored member join the group as a new member; see instructions in Rebuild the Failed Member to Rejoin as a New Member below on how to do that.

4. **Restore the mysqld-auto.cnf file for s3 (only required if s3 used persistent system variables).** The settings for the Section 7.1.9.3, “Persisted System Variables” that were used to configure the failed member must be provided to the restored member. These settings are to be found in the `mysqld-auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See Restoring Persisted System Variables on what to do if you do not have a copy of the file.

5. **Start the restored server.** For example, on Linux distributions that use systemd:

```
systemctl start mysqld
```

**Note**

If the server you are restoring is a primary member, perform the steps described in Restoring a Primary Member before starting the restored server.

6. **Restart Group Replication.** Connect to the restarted `s3` using, for example, a `mysql` client, and issue the following command:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication’s distributed recovery mechanism, and the process starts after the `START`
GROUP_REPLICATION statement has been issued. To check the member status of the restored instance, issue:

```sql
SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
```

<table>
<thead>
<tr>
<th>member_host</th>
<th>member_port</th>
<th>member_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>s1</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>s2</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>s3</td>
<td>3306</td>
<td>RECOVERING</td>
</tr>
</tbody>
</table>

This shows that s3 is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its member_state changes to ONLINE:

```sql
SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
```

<table>
<thead>
<tr>
<th>member_host</th>
<th>member_port</th>
<th>member_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>s1</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>s2</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>s3</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
</tbody>
</table>

**Note**

If the server you are restoring is a primary member, once it has gained synchrony with the group and become ONLINE, perform the steps described at the end of Restoring a Primary Member to revert the configuration changes you had made to the server before you started it.

The member has now been fully restored from the backup and functions as a regular member of the group.

**Rebuild the Failed Member to Rejoin as a New Member**

Sometimes, the steps outlined above in Restoring a Failed Member cannot be carried out because, for example, the binary log or relay log is corrupted, or it is just missing from the backup. In such a situation, use the backup to rebuild the member, and then add it to the group as a new member. In the steps below, we assume the rebuilt member is named s3, like the failed member, and that it runs on the same host as s3:

1. **Copy the backup of s2 onto the host for s3**. The exact way to copy the backup depends on the operating system and tools available to you. In this example we assume the hosts are both Linux servers and use SCP to copy the files between them:

   ```bash
   s2/backups> scp my.mbi_2206_1429 s3:/backups
   ```

2. **Restore the backup**. Connect to the target host (the host for s3 in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

   a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

   ```bash
   s3> systemctl stop mysqld
   ```

   b. Preserve the configuration file `mysqld-auto.cnf`, if it is found in the corrupted server's data directory, by copying it to a safe location outside of the data directory. This is for preserving the server's Section 7.1.9.3, “Persisted System Variables”, which are needed later.

   c. Delete all contents in the data directory of s3. For example:

   ```bash
   s3> rm -rf /var/lib/mysql/*
   ```
If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

d. Restore the backup of `s2` onto the host of `s3`. With this approach, we are rebuilding `s3` as a new member, for which we do not need or do not want to use the old binary and relay logs in the backup; therefore, if these logs have been included in your backup, exclude them using the `--skip-binlog` and `--skip-relaylog` options:

```bash
s3> mysqlbackup --defaults-file=/etc/my.cnf \
    --datadir=/var/lib/mysql \
    --backup-image=/backups/my.mbi_2206_1429 \
    --backup-dir=/tmp/restore_`date +%d%m_%H%M` \
    --skip-binlog --skip-relaylog \
    copy-back-and-apply-log
```

**Note**

If you have healthy binary log and relay logs in the backup that you can transfer onto the target host with no issues, you are recommended to follow the easier procedure as described in Restoring a Failed Member above.

3. Restore the `mysqld-auto.cnf` file for `s3` (only required if `s3` used persistent system variables). The settings for the Section 7.1.9.3, “Persisted System Variables” that were used to configure the failed member must be provided to the restored server. These settings are to be found in the `mysqld-auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See Restoring Persisted System Variables on what to do if you do not have a copy of the file.

**Note**

Do NOT restore the corrupted server's `auto.cnf` file to the data directory of the new member—when the rebuilt `s3` joins the group as a new member, it is going to be assigned a new server UUID.

4. **Start the restored server.** For example, on Linux distributions that use systemd:

```bash
systemctl start mysqld
```

**Note**

If the server you are restoring is a primary member, perform the steps described in Restoring a Primary Member before starting the restored server.

5. **Reconfigure the restored member to join Group Replication.** Connect to the restored server with a `mysql` client and reset the source and replica information with the following commands:

```bash
mysql> RESET BINARY LOGS AND GTIDS;
mysql> RESET REPLICA ALL;
```

For the restored server to be able to recover automatically using Group Replication's built-in mechanism for distributed recovery, configure the server's `gtid_executed` variable. To do this, use the `backup_gtid_executed.sql` file included in the backup of `s2`, which is usually restored under the restored member’s data directory. Disable binary logging, use the `backup_gtid_executed.sql` file to configure `gtid_executed`, and then re-enable binary logging by issuing the following statements with your `mysql` client:

```bash
mysql> SET SQL_LOG_BIN=OFF;
mysql> SOURCE datadir/backup_gtid_executed.sql
```
Using MySQL Enterprise Backup with Group Replication

mysql> SET SQL_LOG_BIN=ON;

Then, configure the Group Replication user credentials on the member:

mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user',
   -> SOURCE_PASSWORD='password',
   -> FOR CHANNEL 'group_replication_recovery';

6. **Restart Group Replication.** Issue the following command to the restored server with your `mysql` client:

    mysql> START GROUP_REPLICATION;

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's distributed recovery mechanism, and the process starts after the `START GROUP_REPLICATION` statement has been issued. To check the member status of the restored instance, issue:

    mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;

<table>
<thead>
<tr>
<th>member_host</th>
<th>member_port</th>
<th>member_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>s3</td>
<td>3306</td>
<td>RECOVERING</td>
</tr>
<tr>
<td>s2</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>s1</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
</tbody>
</table>

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

    mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;

<table>
<thead>
<tr>
<th>member_host</th>
<th>member_port</th>
<th>member_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>s3</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>s2</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>s1</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
</tbody>
</table>

**Note**

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of Restoring a Primary Member to revert the configuration changes you had made to the server before you started it.

The member has now been restored to the group as a new member.

**Restoring Persisted System Variables.** `mysqlbackup` does not provide support for backing up or preserving Section 7.1.9.3, “Persisted System Variables”—the file `mysqld-auto.cnf` is not included in a backup. To start the restored member with its persisted variable settings, you need to do one of the following:

- Preserve a copy of the `mysqld-auto.cnf` file from the corrupted server, and copy it to the restored server’s data directory.

- Copy the `mysqld-auto.cnf` file from another member of the group into the restored server’s data directory, if that member has the same persisted system variable settings as the corrupted member.

- After the restored server is started and before you restart Group Replication, set all the system variables manually to their persisted values through a `mysql` client.

**Restoring a Primary Member.** If the restored member is a primary in the group, care must be taken to prevent writes to the restored database during the Group Replication distributed recovery process.
Depending on how the group is accessed by clients, there is a possibility of DML statements being executed on the restored member once it becomes accessible on the network, prior to the member finishing its catch-up on the activities it has missed while off the group. To avoid this, before starting the restored server, configure the following system variables in the server option file:

```plaintext
GROUP_REPLICATION_START_ON_BOOT=OFF
SUPER_READ_ONLY=ON
EVENT_SCHEDULER=OFF
```

These settings ensure that the member becomes read-only at startup and that the event scheduler is turned off while the member is catching up with the group during the distributed recovery process. Adequate error handling must also be configured on the clients, as they are prevented temporarily from performing DML operations during this period on the restored member. Once the restore process is fully completed and the restored member is in-sync with the rest of the group, revert those changes; restart the event scheduler:

```sql
mysql> SET GLOBAL EVENT_SCHEDULER=ON;
```

Edit the following system variables in the member's option file, so things are correctly configured for the next startup:

```plaintext
GROUP_REPLICATION_START_ON_BOOT=ON
SUPER_READ_ONLY=OFF
EVENT_SCHEDULER=ON
```

## 20.6 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using an IP address allowlist.

### 20.6.1 Communication Stack for Connection Security Management

MySQL 8.4 Group Replication can secure group communication connections between members by one of the following methods:

- Using its own implementation of the security protocols, including TLS/SSL and the use of an allowlist for incoming Group Communication System (GCS) connections.
- Using MySQL Server’s own connection security in place of Group Replication’s implementation. Using the MySQL protocol means that standard methods of user authentication can be used for granting (or revoking) access to the group in place of the allowlist, and the latest functionality of the server’s protocol is always available on release.

The choice is made by setting the system variable `GROUP_REPLICATION_COMMUNICATION_STACK` to `XCOM` to use Group Replication’s own implementation (this is the default choice), or to `MYSQL` to use MySQL Server's connection security.

The following additional configuration is required for a replication group to use the MySQL communication stack. It is especially important to make sure these requirements are all fulfilled when you switch from using the XCom communication stack to the MySQL communication stack for your group.

### Group Replication Requirements For The MySQL Communication Stack

- The network address configured by the `GROUP_REPLICATION_LOCAL_ADDRESS` system variable for each group member must be set to one of the IP addresses and ports that MySQL Server is listening on, as specified by the `BIND_ADDRESS` system variable for the server. The combination of IP address and port for each member must be unique in the group. It is recommended that the `GROUP_REPLICATION_GROUP_SEEDS` system variable for each group member be configured to contain all the local addresses for all the group members.
• The MySQL communication stack supports network namespaces, which the XCom communication stack does not support. If network namespaces are used with the Group Replication local addresses for the group members (group_replication_local_address), these must be configured for each group member using the CHANGE REPLICATION SOURCE TO statement. Also, the report_host server system variable for each group member must be set to report the namespace. All group members must use the same namespace to avoid possible issues with address resolution during distributed recovery.

• The group_replication_ssl_mode system variable must be set to the required setting for group communications. This system variable controls whether TLS/SSL is enabled or disabled for group communications. When the MySQL communication stack is used, the TLS/SSL configuration is taken from Group Replication’s distributed recovery settings. This setting should be the same on all the group members, to avoid potential conflicts.

• The require_secure_transport server system variable value should be the same on all the group members, to avoid potential conflicts. If group_replication_ssl_mode is set to REQUIRED, VERIFY_CA, or VERIFY_IDENTITY, use require_secure_transport=ON. If group_replication_ssl_mode is set to DISABLED, use require_secure_transport=OFF.

• If TLS/SSL is enabled for group communications, Group Replication’s settings for securing distributed recovery must be configured if they are not already in place, or validated if they already are. The MySQL communication stack uses these settings not just for member-to-member distributed recovery connections, but also for TLS/SSL configuration in general group communications. group_replication_recovery_use_ssl and the other group_replication_recovery_* system variables are explained in Section 20.6.3.2, “Secure Socket Layer (SSL) Connections for Distributed Recovery”.

• The Group Replication allowlist is not used when the group is using the MySQL communication stack, so the group_replication_ip_allowlist system variable is ignored and need not be set.

• The replication user account that Group Replication uses for distributed recovery, as configured using the CHANGE REPLICATION SOURCE TO statement, is used for authentication by the MySQL communication stack when setting up Group Replication connections. This user account, which is the same on all group members, must be given the following privileges:

  • GROUP_REPLICATION_STREAM. This privilege is required for the user account to be able to establish connections for Group Replication using the MySQL communication stack.

  • CONNECTION_ADMIN. This privilege is required so that Group Replication connections are not terminated if one of the servers involved is placed in offline mode. If the MySQL communication stack is in use without this privilege, a member that is placed in offline mode is expelled from the group.

These are in addition to the privileges REPLICATION_SLAVE and BACKUP_ADMIN that all replication user accounts must have (see Section 20.2.1.3, “User Credentials For Distributed Recovery”). When you add the new privileges, ensure that you skip binary logging on each group member by issuing SET SQL_LOG_BIN=0 before you issue the GRANT statements, and SET SQL_LOG_BIN=1 after them, so that the local transaction does not interfere with restarting Group Replication.

group_replication_communication_stack is effectively a group-wide configuration setting, and the setting must be the same on all group members. However, this is not policed by Group Replication’s own checks for group-wide configuration settings. A member with a different value from the rest of the group cannot communicate with the other members at all, because the communication protocols are incompatible, so it cannot exchange information about its configuration settings.

This means that although the value of the system variable can be changed while Group Replication is running, and takes effect after you restart Group Replication on the group member, the member still cannot rejoin the group until the setting has been changed on all the members. You must therefore stop Group Replication on all of the members and change the value of the system variable on them all.
before you can restart the group. Because all of the members are stopped, a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) is required in order for the value change to take effect. You can make the other required changes to settings on the group members while they are stopped.

For a running group, follow this procedure to change the value of `group_replication_communication_stack` and the other required settings to migrate a group from the XCom communication stack to the MySQL communication stack, or from the MySQL communication stack to the XCom communication stack:

1. Stop Group Replication on each of the group members, using a `STOP GROUP_REPLICATION` statement. Stop the primary member last, so that you do not trigger a new primary election and have to wait for that to complete.

2. On each of the group members, set the system variable `group_replication_communication_stack` to the new communication stack, `MYSQL` or `XCOM` as appropriate. You can do this by editing the MySQL Server configuration file (typically named `my.cnf` on Linux and Unix systems, or `my.ini` on Windows systems), or by using a `SET` statement. For example:

   ```sql
   SET PERSIST group_replication_communication_stack="MYSQL";
   ```

3. If you are migrating the replication group from the XCom communication stack (the default) to the MySQL communication stack, on each of the group members, configure or reconfigure the required system variables to appropriate settings, as described in the listing above. For example, the `group_replication_local_address` system variable must be set to one of the IP addresses and ports that MySQL Server is listening on. Also configure any network namespaces using a `CHANGE REPLICATION SOURCE TO` statement.

4. If you are migrating the replication group from the XCom communication stack (the default) to the MySQL communication stack, on each of the group members, issue `GRANT` statements to give the replication user account the `GROUP_REPLICATION_STREAM` and `CONNECTION_ADMIN` privileges. You will need to take the group members out of the read-only state that is applied when Group Replication is stopped. Also ensure that you skip binary logging on each group member by issuing `SET SQL_LOG_BIN=0` before you issue the `GRANT` statements, and `SET SQL_LOG_BIN=1` after them, so that the local transaction does not interfere with restarting Group Replication. For example:

   ```sql
   SET GLOBAL SUPER_READ_ONLY=OFF;
   SET SQL_LOG_BIN=0;
   GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%%';
   GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%%';
   SET SQL_LOG_BIN=1;
   ```

5. If you are migrating the replication group from the MySQL communication stack back to the XCom communication stack, on each of the group members, reconfigure the system variables in the requirements listing above to settings suitable for the XCom communication stack. Section 20.9, “Group Replication Variables” lists the system variables with their defaults and requirements for the XCom communication stack.

Note

- The XCom communication stack does not support network namespaces, so the Group Replication local address (`group_replication_local_address` system variable) cannot use these. Unset them by issuing a `CHANGE REPLICATION SOURCE TO` statement.

- When you move back to the XCom communication stack, the settings specified by `group_replication_recovery_use_ssl` and the other `group_replication_recovery_*` system variables are not used to secure group communications. Instead, the Group Replication system
variable `group_replication_ssl_mode` is used to activate the use of
SSL for group communication connections and specify the security mode
for the connections, and the remainder of the configuration is taken from
the server's SSL configuration. For details, see Section 20.6.2, “Securing
Group Communication Connections with Secure Socket Layer (SSL)”.

6. To restart the group, follow the process in Section 20.5.2, “Restarting a Group”, which explains
how to safely bootstrap a group where transactions have been executed and certified. A bootstrap
by a server with `group_replication_bootstrap_group=ON` is necessary to change the
communication stack, because all of the members must be shut down.

7. Members now connect to each other using the new communication stack. Any server that has
`group_replication_communication_stack` set (or defaulted, in the case of XCom) to
the previous communication stack is no longer able to join the group. It is important to note that
because Group Replication cannot even see the joining attempt, it does not check and reject the
joining member with an error message. Instead, the attempted join fails silently when the previous
communication stack gives up trying to contact the new one.

### 20.6.2 Securing Group Communication Connections with Secure Socket
Layer (SSL)

Secure sockets can be used for group communication connections between members of a group.

The Group Replication system variable `group_replication_ssl_mode` is used to activate the use
of SSL for group communication connections and specify the security mode for the connections. The
default setting means that SSL is not used. The option has the following possible values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISABLED</td>
<td>Establish an unencrypted connection (the default).</td>
</tr>
<tr>
<td>REQUIRED</td>
<td>Establish a secure connection if the server supports secure connections.</td>
</tr>
<tr>
<td>VERIFY_CA</td>
<td>Like REQUIRED, but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.</td>
</tr>
<tr>
<td>VERIFY_IDENTITY</td>
<td>Like VERIFY_CA, but additionally verify that the server certificate matches the host to which the connection is attempted.</td>
</tr>
</tbody>
</table>

If SSL is used, the means for configuring the secure connection depends on whether the XCom or the
MySQL communication stack is used for group communication.

#### When using the XCom communication stack

(group_replication_communication_stack=XCOM): The remainder of the configuration for
Group Replication's group communication connections is taken from the server's SSL configuration.
For more information on the options for configuring the server SSL, see Command Options for
Encrypted Connections. The server SSL options that are applied to Group Replication's group
communication connections are as follows:

<table>
<thead>
<tr>
<th>Server Configuration</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssl_key</td>
<td>The path name of the SSL private key file in PEM format. On the client side, this is the client private</td>
</tr>
</tbody>
</table>
Securing Group Communication Connections with Secure Socket Layer (SSL)

<table>
<thead>
<tr>
<th>Server Configuration</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssl_cert</td>
<td>The path name of the SSL public key certificate file in PEM format. On the client side, this is the client public key certificate. On the server side, this is the server public key certificate.</td>
</tr>
<tr>
<td>ssl_ca</td>
<td>The path name of the Certificate Authority (CA) certificate file in PEM format.</td>
</tr>
<tr>
<td>ssl_capath</td>
<td>The path name of the directory that contains trusted SSL certificate authority (CA) certificate files in PEM format.</td>
</tr>
<tr>
<td>ssl_crl</td>
<td>The path name of the file containing certificate revocation lists in PEM format.</td>
</tr>
<tr>
<td>ssl_crlpath</td>
<td>The path name of the directory that contains certificate revocation list files in PEM format.</td>
</tr>
<tr>
<td>ssl_cipher</td>
<td>A list of permissible ciphers for encrypted connections.</td>
</tr>
<tr>
<td>tls_version</td>
<td>A list of the TLS protocols the server permits for encrypted connections.</td>
</tr>
<tr>
<td>tls_ciphersuites</td>
<td>Which TLSv1.3 ciphersuites the server permits for encrypted connections.</td>
</tr>
</tbody>
</table>

### Important

- Support for the TLSv1 and TLSv1.1 connection protocols was removed in MySQL 8.0. MySQL clients, including Group Replication server instances acting as clients, do not return warnings to the user if a deprecated TLS protocol version is used. See [Removal of Support for the TLSv1 and TLSv1.1 Protocols](#) for more information.

- MySQL 8.4 supports the TLSv1.3 protocol, provided that the MySQL Server was compiled using OpenSSL 1.1.1. The server checks the version of OpenSSL at startup; if it is lower than 1.1.1, TLSv1.3 is removed from the default values for all server system variables relating to TLS versions, including `group_replication_recovery_tls_version`.

- MySQL 8.4 Group Replication supports TLSv1.3.

- Use `group_replication_recovery_tls_version` and `group_replication_recovery_tls_ciphersuites` to configure client support for any selection of ciphersuites, including only non-default ciphersuites if desired.

- In the list of TLS protocols specified in the `tls_version` system variable, ensure the specified versions are contiguous (for example, `TLSv1.2,TLSv1.3`). If there are any gaps in the list of protocols (for example, if you specified `TLSv1,TLSv1.2`, omitting TLS 1.1) Group Replication might be unable to make group communication connections.

In a replication group, OpenSSL negotiates the use of the highest TLS protocol that is supported by all members. A joining member that is configured to use only TLSv1.3 (`tls_version=TLSv1.3`) cannot join a replication group where any existing member does not support TLSv1.3, because the group members in that case are using a lower TLS protocol version. To join the member to the group, you must configure the joining member to also permit the use of lower TLS protocol versions supported by the existing group members. Conversely, if a joining member does not support TLSv1.3, but the
existing group members all do and are using that version for connections to each other, the member can join if the existing group members already permit the use of a suitable lower TLS protocol version, or if you configure them to do so. In that situation, OpenSSL uses a lower TLS protocol version for the connections from each member to the joining member. Each member's connections to other existing members continue to use the highest available protocol that both members support.

You can change the `tls_version` system variable at runtime to alter the list of permitted TLS protocol versions for the server. For Group Replication, the `ALTER INSTANCE RELOAD TLS` statement, which reconfigures the server's TLS context from the current values of the system variables that define the context, does not change the TLS context for Group Replication's group communication connection while Group Replication is running. To apply the reconfiguration to these connections, you must execute `STOP_GROUP_REPLICATION` followed by `START_GROUP_REPLICATION` to restart Group Replication on the member or members where you changed the `tls_version` system variable. Similarly, if you want to make all members of a group change to using a higher or lower TLS protocol version, you must carry out a rolling restart of Group Replication on the members after changing the list of permitted TLS protocol versions, so that OpenSSL negotiates the use of the higher TLS protocol version when the rolling restart is completed. For instructions to change the list of permitted TLS protocol versions at runtime, see Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers” and Server-Side Runtime Configuration and Monitoring for Encrypted Connections.

The following example shows a section from a `my.cnf` file that configures SSL on a server, and activates SSL for Group Replication group communication connections:

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "/.../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AES256-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "/.../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

Important
---
The `ALTER INSTANCE RELOAD TLS` statement, which reconfigures the server's TLS context from the current values of the system variables that define the context, does not change the TLS context for Group Replication's group communication connections while Group Replication is running. To apply the reconfiguration to these connections, you must execute `STOP_GROUP_REPLICATION` followed by `START_GROUP_REPLICATION` to restart Group Replication.

Connections made between a joining member and an existing member for distributed recovery are not covered by the options described above. These connections use Group Replication's dedicated distributed recovery SSL options, which are described in Section 20.6.3.2, “Secure Socket Layer (SSL) Connections for Distributed Recovery”.

When using the MySQL communication stack `(group_replication_communication_stack=MYSQL)`: The security settings for distributed recovery of the group are applied to the normal communications between group members. See Section 20.6.3, “Securing Distributed Recovery Connections” on how to configure the security settings.

20.6.3 Securing Distributed Recovery Connections

Important
---
When using the MySQL communication stack `(group_replication_communication_stack=MYSQL)` AND secure connections between members `(group_replication_ssl_mode` is not set to `DISABLED`), the security settings discussed in this section are applied not
just to distributed recovery connections, but to group communications between members in general.

When a member joins the group, distributed recovery is carried out using a combination of a remote cloning operation, if available and appropriate, and an asynchronous replication connection. For a full description of distributed recovery, see Section 20.5.4, “Distributed Recovery”.

Group members offer their standard SQL client connection to joining members for distributed recovery, as specified by MySQL Server’s `hostname` and `port` system variables, and may (also) advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members. For more details, see Section 20.5.4.1, “Connections for Distributed Recovery”. Notice that such connections offered to a joining member for distributed recovery is not the same connections that are used by Group Replication for communication between online members when the XCom communication stack is used for group communications (`group_replication_communication_stack=XCOM`).

To secure distributed recovery connections in the group, ensure that user credentials for the replication user are properly secured, and use SSL for distributed recovery connections if possible.

### 20.6.3.1 Secure User Credentials for Distributed Recovery

State transfer from the binary log requires a replication user with the correct permissions so that Group Replication can establish direct member-to-member replication channels. The same replication user is used for distributed recovery on all the group members. If group members have been set up to support the use of a remote cloning operation as part of distributed recovery, this replication user is also used as the clone user on the donor, and requires the correct permissions for this role. For detailed instructions to set up this user, see Section 20.2.1.3, “User Credentials For Distributed Recovery”.

To secure the user credentials, you can require SSL for connections with the user account, and provide the user credentials when Group Replication is started, rather than storing them in the replica status tables. Also, if you are using caching SHA-2 authentication, you must set up RSA key-pairs on the group members.

---

Important

When using the MySQL communication stack (`group_replication_communication_stack=MYSQL`) AND secure connections between members (`group_replication_ssl_mode` is not set to `DISABLED`), the recovery users must be properly set up, as they are also the users for group communications. Follow the instructions in Replication User With SSL and Providing Replication User Credentials Securely.

---

Replication User With The Caching SHA-2 Authentication Plugin

By default, users created in MySQL 8 use Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”. If the replication user you configure for distributed recovery uses the caching SHA-2 authentication plugin, and you are not using SSL for distributed recovery connections, RSA key-pairs are used for password exchange. For more information on RSA key-pairs, see Section 8.3.3, “Creating SSL and RSA Certificates and Keys”.

In this situation, you can either copy the public key of the `rpl_user` to the joining member, or configure the donors to provide the public key when requested. The more secure approach is to copy the public key of the replication user account to the joining member. Then you need to configure the `group_replication_recovery_public_key_path` system variable on the joining member with the path to the public key for the replication user account.

The less secure approach is to set `group_replication_recovery_get_public_key=ON` on donors so that they provide the public key of the replication user account to joining members. There is no way to verify the identity of a server, therefore only set `group_replication_recovery_get_public_key=ON` when you are sure there is no risk of server identity being compromised, for example by a man-in-the-middle attack.
Replication User With SSL

A replication user that requires an SSL connection must be created before the server joining the group (the joining member) connects to the donor. Typically, this is set up at the time you are provisioning a server to join the group. To create a replication user for distributed recovery that requires an SSL connection, issue these statements on all servers that are going to participate in the group:

```sql
mysql> SET SQL_LOG_BIN=0;
mysql> CREATE USER 'rec_ssl_user'@'%' IDENTIFIED BY 'password' REQUIRE SSL;
mysql> GRANT REPLICATION SLAVE ON *.* TO 'rec_ssl_user'@'%';
mysql> GRANT CONNECTION_ADMIN ON *.* TO 'rec_ssl_user'@'%';
mysql> GRANT BACKUP_ADMIN ON *.* TO 'rec_ssl_user'@'%';
mysql> GRANT GROUP_REPLICATION_STREAM ON *.* TO rec_ssl_user@'%';
mysql> FLUSH PRIVILEGES;
mysql> SET SQL_LOG_BIN=1;
```

**Note**

The `GROUP_REPLICATION_STREAM` privilege is required when using both the MySQL communication stack (`group_replication_communication_stack=MYSQL`) and secure connections between members (`group_replication_ssl_mode` not set to `DISABLED`). See Section 20.6.1, “Communication Stack for Connection Security Management”.

Providing Replication User Credentials Securely

To supply the user credentials for the replication user, you can set them permanently as the credentials for the `group_replication_recovery` channel, using a `CHANGE REPLICATION SOURCE TO` statement. Alternatively, you can specify them in the `START GROUP_REPLICATION` statement each time Group Replication is started. User credentials specified in `START GROUP_REPLICATION` take precedence over any user credentials that have been set using a `CHANGE REPLICATION SOURCE TO` statement.

User credentials set using `CHANGE REPLICATION SOURCE TO` are stored in plain text in the replication metadata repositories on the server, but user credentials specified on `START GROUP_REPLICATION` are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. Using `START GROUP_REPLICATION` to specify the user credentials therefore helps to secure the Group Replication servers against unauthorized access. However, this method is not compatible with starting Group Replication automatically, as specified by the `group_replication_start_on_boot` system variable.

If you want to set the user credentials permanently using a `CHANGE REPLICATION SOURCE TO` statement, issue this statement on the member that is going to join the group:

```sql
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rec_ssl_user',
   -> SOURCE_PASSWORD='password'
   -> FOR CHANNEL 'group_replication_recovery';
```

To supply the user credentials on `START GROUP_REPLICATION`, issue this statement when starting Group Replication for the first time, or after a server restart:

```sql
mysql> START GROUP_REPLICATION USER='rec_ssl_user', PASSWORD='password';
```

**Important**

If you switch to using `START GROUP_REPLICATION` to specify user credentials on a server that previously supplied the credentials using `CHANGE REPLICATION SOURCE TO`, you must complete the following steps to get the security benefits of this change.

1. Stop Group Replication on the group member using a `STOP GROUP_REPLICATION` statement.
   Although it is possible to take the following two steps while Group Replication is running, you need to restart Group Replication to implement the changes.

---

3617
2. Set the value of the `group_replication_start_on_boot` system variable to `OFF` (the default is `ON`).

3. Remove the distributed recovery credentials from the replica status tables by issuing this statement:

```sql
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='', SOURCE_PASSWORD='' -> FOR CHANNEL 'group_replication_recovery';
```

4. Restart Group Replication on the group member using a `START GROUP_REPLICATION` statement that specifies the distributed recovery user credentials.

Without these steps, the credentials remain stored in the replica status tables, and can also be transferred to other group members during remote cloning operations for distributed recovery. The `group_replication_recovery` channel could then be inadvertently started with the stored credentials, on either the original member or members that were cloned from it. An automatic start of Group Replication on server boot (including after a remote cloning operation) would use the stored user credentials, and they would also be used if an operator did not specify the distributed recovery credentials as part of `START GROUP_REPLICATION`.

### 20.6.3.2 Secure Socket Layer (SSL) Connections for Distributed Recovery

#### Important

When using the MySQL communication stack (`group_replication_communication_stack=MYSQL`) AND secure connections between members (`group_replication_ssl_mode` is not set to `DISABLED`), the security settings discussed in this section are applied not just to distributed recovery connections, but to group communications between members in general. See Section 20.6.1, “Communication Stack for Connection Security Management”.

Whether the distributed recovery connection is made using the standard SQL client connection or a distributed recovery endpoint, to configure the connection securely, you can use Group Replication's dedicated distributed recovery SSL options. These options correspond to the server SSL options that are used for group communication connections, but they are only applied for distributed recovery connections. By default, distributed recovery connections do not use SSL, even if you activated SSL for group communication connections, and the server SSL options are not applied for distributed recovery connections. You must configure these connections separately.

If a remote cloning operation is used as part of distributed recovery, Group Replication automatically configures the clone plugin's SSL options to match your settings for the distributed recovery SSL options. (For details of how the clone plugin uses SSL, see Configuring an Encrypted Connection for Cloning.)

The distributed recovery SSL options are as follows:

- `group_replication_recovery_use_ssl`: Set to `ON` to make Group Replication use SSL for distributed recovery connections, including remote cloning operations and state transfer from a donor's binary log. If the server you connect to does not use the default configuration for this (see Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”), use the other distributed recovery SSL options to determine which certificates and cipher suites to use.

- `group_replication_recovery_ssl_ca`: The path name of the Certificate Authority (CA) file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_ca` to match this.

- `group_replication_recovery_ssl_capath`: The path name of a directory that contains trusted SSL certificate authority (CA) certificate files.

- `group_replication_recovery_ssl_cert`: The path name of the SSL public key certificate file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_cert` to match this.
- **group_replication_recovery_ssl_key**: The path name of the SSL private key file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_cert` to match this.

- **group_replication_recovery_ssl_verify_server_cert**: Makes the distributed recovery connection check the server's Common Name value in the donor sent certificate. Setting this option to `ON` is equivalent for distributed recovery connections of setting `VERIFY_IDENTITY` for the `group_replication_ssl_mode` option for group communication connections.

- **group_replication_recovery_ssl_crl**: The path name of a file containing certificate revocation lists.

- **group_replication_recovery_ssl_crlpath**: The path name of a directory containing certificate revocation lists.

- **group_replication_recovery_ssl_cipher**: A list of permissible ciphers for connection encryption for the distributed recovery connection. Specify a list of one or more cipher names, separated by colons. For information about which encryption ciphers MySQL supports, see Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

- **group_replication_recovery_tls_version**: A comma-separated list of one or more permitted TLS protocols for connection encryption when this server instance is the client in the distributed recovery connection, that is, the joining member. The default for this system variable depends on the TLS protocol versions supported in the MySQL Server release. The group members involved in each distributed recovery connection as the client (joining member) and server (donor) negotiate the highest protocol version that they are both set up to support.

- **group_replication_recovery_tls_ciphersuites**: A colon-separated list of one or more permitted ciphersuites when TLSv1.3 is used for connection encryption for the distributed recovery connection, and this server instance is the client in the distributed recovery connection, that is, the joining member. If this system variable is set to `NULL` when TLSv1.3 is used (which is the default if you do not set the system variable), the ciphersuites that are enabled by default are allowed, as listed in Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”. If this system variable is set to the empty string, no cipher suites are allowed, and TLSv1.3 is therefore not used.

### 20.6.4 Group Replication IP Address Permissions

When and only when the XCom communication stack is used for establishing group communications (`group_replication_communication_stack=XCOM`), the Group Replication plugin lets you specify an allowlist of hosts from which an incoming Group Communication System connection can be accepted. If you specify an allowlist on a server s1, then when server s2 is establishing a connection to s1 for the purpose of engaging group communication, s1 first checks the allowlist before accepting the connection from s2. If s2 is in the allowlist, then s1 accepts the connection, otherwise s1 rejects the connection attempt by s2. The system variable `group_replication_ip_allowlist` is used to specify the allowlist.

**Note**

When the MySQL communication stack is used for establishing group communications (`group_replication_communication_stack=MYSQL`), the setting for `group_replication_ip_allowlist` is ignored. See Section 20.6.1, “Communication Stack for Connection Security Management”.

If you do not specify an allowlist explicitly, the group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks, together with the subnet mask that is configured for each interface. These addresses, and the `localhost` IP address for IPv4 and IPv6 are used to create an automatic Group Replication allowlist. The automatic allowlist therefore includes any IP addresses that are found for the host in the following ranges after the appropriate subnet mask has been applied:

- IPv4 (as defined in RFC 1918)
Group Replication IP Address Permissions

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Address Range</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>10/8 prefix</td>
<td>(10.0.0.0 - 10.255.255.255)</td>
<td>Class A</td>
</tr>
<tr>
<td>172.16/12 prefix</td>
<td>(172.16.0.0 - 172.31.255.255)</td>
<td>Class B</td>
</tr>
<tr>
<td>192.168/16 prefix</td>
<td>(192.168.0.0 - 192.168.255.255)</td>
<td>Class C</td>
</tr>
</tbody>
</table>

IPv6 (as defined in RFC 4193 and RFC 5156)
- fc00:/7 prefix - unique-local addresses
- fe80::/10 prefix - link-local unicast addresses

127.0.0.1 - localhost for IPv4
::1 - localhost for IPv6

An entry is added to the error log stating the addresses that have been allowed automatically for the host.

The automatic allowlist of private addresses cannot be used for connections from servers outside the private network, so a server, even if it has interfaces on public IPs, does not by default allow Group Replication connections from external hosts. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit allowlist. If you specify any entries for the allowlist, the private and localhost addresses are not added automatically, so if you use any of these, you must specify them explicitly.

To specify an allow list manually, use the `group_replication_ip_allowlist` system variable. You can change the list while Group Replication is running.

The allowlist must contain the IP address or host name that is specified in each member’s `group_replication_local_address` system variable. This address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. If a host name used as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is preferred for Group Replication connections.

IP addresses specified as distributed recovery endpoints, and the IP address for the member’s standard SQL client connection if that is used for distributed recovery (which is the default), do not need to be added to the allowlist. The allowlist is only for the address specified by `group_replication_local_address` for each member. A joining member must have its initial connection to the group permitted by the allowlist in order to retrieve the address or addresses for distributed recovery.

In the allowlist, you can specify any combination of the following:

- **IPv4 addresses** (for example, `198.51.100.44`)
- **IPv4 addresses with CIDR notation** (for example, `192.0.2.21/24`)
- **IPv6 addresses** (for example, `2001:db8:85a3:8d3:1319:8a2e:370:7348`)
- **IPv6 addresses with CIDR notation** (for example, `2001:db8:85a3:8d3::/64`)
- **Host names** (for example, `example.org`)
- **Host names with CIDR notation** (for example, `www.example.com/24`)

Host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can use CIDR notation in combination with host names or IP addresses to permit a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

**Note**

When a connection attempt from an IP address is refused because the address is not in the allowlist, the refusal message always prints the IP address in IPv6 format. IPv4 addresses are preceded by `::ffff:` in this format (an IPv4-
mapped IPv6 address). You do not need to use this format to specify IPv4 addresses in the allowlist; use the standard IPv4 format for them.

A comma must separate each entry in the allowlist. For example:

```
mysql> SET GLOBAL group_replication_ip_allowlist="192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,example.org,www.example.com/24";
```

To join a replication group, a server needs to be permitted on the seed member to which it makes the request to join the group. Typically, this would be the bootstrap member for the replication group, but it can be any of the servers listed by the `group_replication_group_seeds` option in the configuration for the server joining the group. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and permit an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). This is because when a server joins a replication group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information on managing mixed IPv4 and IPv6 replication groups, see Section 20.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.

When a replication group is reconfigured (for example, when a new primary is elected or a member joins or leaves), the group members re-establish connections between themselves. If a group member is only permitted by servers that are no longer part of the replication group after the reconfiguration, it is unable to reconnect to the remaining servers in the replication group that do not permit it. To avoid this scenario entirely, specify the same allowlist for all servers that are members of the replication group.

**Note**
It is possible to configure different allowlists on different group members according to your security requirements, for example, in order to keep different subnets separate. If you need to configure different allowlists to meet your security requirements, ensure that there is sufficient overlap between the allowlists in the replication group to maximize the possibility of servers being able to reconnect in the absence of their original seed member.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for allowlist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

**Warning**
Host names are inherently less secure than IP addresses in an allowlist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

## 20.7 Group Replication Performance and Troubleshooting

Group Replication is designed to create fault-tolerant systems with built-in failure detection and automated recovery. If a member server instance leaves voluntarily or stops communicating with the group, the remaining members agree a reconfiguration of the group between themselves, and choose a new primary if needed. Expelled members automatically attempt to rejoin the group, and are brought up to date by distributed recovery. If a group experiences a level of difficulties such that it cannot contact a majority of its members in order to agree on a decision, it identifies itself as having lost quorum and stops processing transactions. Group Replication also has built-in mechanisms and
settings to help the group adapt to and manage variations in workload and message size, and stay within the limitations of the underlying system and networking resources.

The default settings for Group Replication’s system variables are designed to maximize a group’s performance and autonomy. The information in this section is to help you configure a replication group to optimize the automatic handling of any recurring issues that you experience on your particular systems, such as transient network outages or workloads and transactions that exceed a server instance’s resources.

If you find that group members are being expelled and rejoining the group more frequently than you would like, it is possible that Group Replication’s default failure detection settings are too sensitive for your system. This might be the case on slower networks or machines, networks with a high rate of unexpected transient outages, or during planned network outages. For advice on dealing with that situation by adjusting the settings, see Section 20.7.7, “Responses to Failure Detection and Network Partitioning”.

You should only need to intervene manually in a Group Replication setup if something happens that the group cannot deal with automatically. Some key issues that can require administrator intervention are when a member is in ERROR status and cannot rejoin the group, or when a network partition causes the group to lose quorum.

• If an otherwise correctly functioning and configured member is unable to join or rejoin the group using distributed recovery, and remains in ERROR status, Section 20.5.4.4, “Fault Tolerance for Distributed Recovery”, explains the possible issues. One likely cause is that the joining member has extra transactions that are not present on the existing members of the group. For advice on dealing with that situation, see Section 20.4.1, “GTIDs and Group Replication”.

• If a group has lost quorum, this may be due to a network partition that divides the group into two parts, or possibly due to the failure of the majority of the servers. For advice on dealing with that situation, see Section 20.7.8, “Handling a Network Partition and Loss of Quorum”.

20.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT to do an active wait, use the group_replication_poll_spin_loops option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

20.7.2 Flow Control

Group Replication ensures that a transaction only commits after a majority of the members in a group have received it and agreed on the relative order between all transactions that were sent concurrently. This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does and some of the members have less write throughput than others, particularly less than the writer members, those members can start lagging behind of the writers.

Having some members lagging behind the group brings some problematic consequences, particularly, the reads on such members may externalize very old data. Depending on why the member is lagging
behind, other members in the group may have to save more or less replication context to be able to fulfill potential data transfer requests from the slow member.

There is however a mechanism in the replication protocol to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism. It tries to address several goals:

1. to keep the members close enough to make buffering and de-synchronization between members a small problem;
2. to adapt quickly to changing conditions like different workloads or more writers in the group;
3. to give each member a fair share of the available write capacity;
4. to not reduce throughput more than strictly necessary to avoid wasting resources.

Given the design of Group Replication, the decision whether to throttle or not may be decided taking into account two work queues: (i) the certification queue; (ii) and on the binary log applier queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered. Only configure: (i) whether to do flow control at the certifier or at the applier level, or both; and (ii) what is the threshold for each queue.

The flow control depends on two basic mechanisms:

1. the monitoring of members to collect some statistics on throughput and queue sizes of all group members to make educated guesses on what is the maximum write pressure each member should be subjected to;
2. the throttling of members that are trying to write beyond their fair-share of the available capacity at each moment in time.

### 20.7.2.1 Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;
- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

### 20.7.2.2 Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.
Therefore, metrics acquired from all members are the basis for calculating the capacity of each
member: if a member has a large queue (for certification or the applier thread), then the capacity to
execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while
the number of local transactions determines how many members are writing to it, and, consequently,
how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other
words a number of transactions it can safely issue for the next period. The writer-quota is enforced
by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-
defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also
further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to
avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only
allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing
those transactions that exceed it until the end of the monitoring period. As a consequence, if the
quota is very small for the write requests issued some transactions may have latencies close to the
monitoring period.

20.7.3 Single Consensus Leader

By default, the group communication engine for Group Replication (XCom, a Paxos variant) operates
using every member of the replication group as a leader. The group communication engine can use
a single leader to drive consensus when the group is in single-primary mode. Operating with a single
consensus leader improves performance and resilience in single-primary mode, particularly when some
of the group’s secondary members are currently unreachable.

To use a single consensus leader, the group must be configured as follows:

- The group must be in single-primary mode.
- The `group_replication_paxos_single_leader` system variable must be set to `ON`. With the
default setting `OFF`, the behavior is disabled. You must carry out a full reboot of the replication group
(bootstrap) for Group Replication to pick up a change to this setting.
- The Group Replication communication protocol version must be set to 8.0.27 or later. Use the
`group_replication_get_communication_protocol()` function to view the group’s
communication protocol version. If a lower version is in use, the group cannot use this behavior.
You can use the `group_replication_set_communication_protocol()` function to set the
group’s communication protocol to a higher version if all group members support it. MySQL InnoDB
Cluster manages the communication protocol version automatically. For more information, see
Section 20.5.1.4, “Setting a Group’s Communication Protocol Version”.

When this configuration is in place, Group Replication instructs the group communication engine
to use the group’s primary as the single leader to drive consensus. When a new primary is elected,
Group Replication tells the group communication engine to use it instead. If the primary is currently
unhealthy, the group communication engine uses an alternative member as the consensus leader.
The Performance Schema table `replication_group_communication_information` shows the
current preferred and actual consensus leader, with the preferred leader being Group Replication’s
choice, and the actual leader being the one selected by the group communication engine.

If the group is in multi-primary mode, has a lower communication protocol version, or the behavior
is disabled by the `group_replication_paxos_single_leader` setting, all members
are used as leaders to drive consensus. In this situation, the Performance Schema table
`replication_group_communication_information` shows all of the members as both the
preferred and actual leaders.
The field `WRITE_CONSENSUS_SINGLE_LEADER_CAPABLE` in the Performance Schema table `replication_group_communication_information` shows whether the group supports the use of a single leader, even if `group_replication_paxos_single_leader` is currently set to `OFF` on the queried member. The field is set to `1` if the group was started with `group_replication_paxos_single_leader` set to `ON`, and its communication protocol version is MySQL 8.0.27 or above. This information is returned only for group members in `ONLINE` or `RECOVERING` state.

### 20.7.4 Message Compression

For messages sent between online group members, Group Replication enables message compression by default. Whether a specific message is compressed depends on the threshold that you configure using the `group_replication_compression_threshold` system variable. Messages that have a payload larger than the specified number of bytes are compressed.

The default compression threshold is 1000000 bytes. You could use the following statements to increase the compression threshold to 2MB, for example:

```sql
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold = 2097152;
START GROUP_REPLICATION;
```

If you set `group_replication_compression_threshold` to zero, message compression is disabled.

Group Replication uses the LZ4 compression algorithm to compress messages sent in the group. Note that the maximum supported input size for the LZ4 compression algorithm is 2113929216 bytes. This limit is lower than the maximum possible value for the `group_replication_compression_threshold` system variable, which is matched to the maximum message size accepted by XCom. The LZ4 maximum input size is therefore a practical limit for message compression, and transactions above this size cannot be committed when message compression is enabled. With the LZ4 compression algorithm, do not set a value greater than 2113929216 bytes for `group_replication_compression_threshold`.

The value of `group_replication_compression_threshold` is not required by Group Replication to be the same on all group members. However, it is advisable to set the same value on all group members in order to avoid unnecessary rollback of transactions, failure of message delivery, or failure of message recovery.

You can also configure compression for messages sent for distributed recovery by the method of state transfer from a donor's binary log. Compression for these messages, which are sent from a donor already in the group to a joining member, is controlled separately using the `group_replication_recovery_compression_algorithms` and `group_replication_recovery_zstd_compression_level` system variables. For more information, see Section 6.2.8, “Connection Compression Control”.

Binary log transaction compression, enabled by the `binlog_transaction_compression` system variable, can also be used to save bandwidth. The transaction payloads remain compressed when they are transferred between group members. If you use binary log transaction compression in combination with Group Replication's message compression, message compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see Section 7.4.4.5, “Binary Log Transaction Compression”.

Compression for messages sent in the group happens at the group communication engine level, before the data is handed over to the group communication thread, so it takes place within the context of the `mysql` user session thread. If the message payload size exceeds the threshold set by `group_replication_compression_threshold`, the transaction payload is compressed before being sent out to the group, and decompressed when it is received. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the
member decompresses the transaction, before delivering it to the upper layer. This process is shown in the following figure.

Figure 20.13 Compression Support

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load. The TCP peer-to-peer nature of the interconnections between $N$ participants in the group makes the sender send the same amount of data $N$ times. Furthermore, binary logs are likely to exhibit a high compression ratio. This makes compression a compelling feature for Group Replication workloads that contain large transactions.

20.7.5 Message Fragmentation

When an abnormally large message is sent between Group Replication group members, it can result in some group members being reported as failed and expelled from the group. This is because the single thread used by Group Replication’s group communication engine (XCom, a Paxos variant) is occupied processing the message for too long, so some of the group members might report the receiver as
failed. By default, large messages are automatically split into fragments that are sent separately and reassembled by the recipients.

The system variable `group_replication_communication_max_message_size` specifies a maximum message size for Group Replication communications, above which messages are fragmented. The default maximum message size is 10485760 bytes (10 MiB). The greatest permitted value is the same as the maximum value of the `replica_max_allowed_packet` system variable (1 GB). `group_replication_communication_max_message_size` must be less than `replica_max_allowed_packet` because the applier thread cannot handle message fragments larger than the maximum permitted packet size. To switch off fragmentation, specify a zero value for `group_replication_communication_max_message_size`.

As with most other Group Replication system variables, you must restart the Group Replication plugin for the change to take effect. For example:

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_communication_max_message_size= 5242880;
START GROUP_REPLICATION;
```

Message delivery for a fragmented message is considered complete when all the fragments of the message have been received and reassembled by all the group members. Fragmented messages include information in their headers that enables a member joining during message transmission to recover the earlier fragments that were sent before it joined. If the joining member fails to recover the fragments, it expels itself from the group.

The Group Replication communication protocol version in use by the group must allow fragmentation. You can obtain the communication protocol in use by a group using `group_replication_get_communication_protocol()`, which returns the oldest MySQL Server version that the group supports. If necessary, use `group_replication_set_communication_protocol()` to set the communication protocol version high enough (8.0.16 or above) to allow fragmentation. For more information, see Section 20.5.1.4, “Setting a Group’s Communication Protocol Version”.

If a replication group cannot use fragmentation because some members do not support it, the system variable `group_replication_transaction_size_limit` can be used to limit the maximum size of transactions the group accepts. Transactions above this size are rolled back. You can also use `group_replication_member_expel_timeout` to allow additional time (up to an hour) before a member under suspicion of having failed is expelled from the group.

20.7.6 XCom Cache Management

The group communication engine for Group Replication (XCom, a Paxos variant) includes a cache for messages (and their metadata) exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery of missed messages by members that reconnect with the group after a period where they were unable to communicate with the other group members.

A cache size limit can be set for XCom’s message cache using the `group_replication_message_cache_size` system variable. If the cache size limit is reached, XCom removes the oldest entries that have been decided and delivered. The same cache size limit should be set on all group members, because an unreachable member that is attempting to reconnect selects any other member at random for recovery of missed messages. The same messages should therefore be available in each member’s cache.

Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of MySQL Server’s other caches and object pools. Note that the limit set using `group_replication_message_cache_size` applies only to the data stored in the cache, and the cache structures require an additional 50 MB of memory.

When choosing the value for `group_replication_message_cache_size`, do so with regard to the expected volume of messages in the period before a member is expelled. The length of this
period is controlled by the `group_replication_member_expel_timeout` system variable, which determines the waiting period (up to an hour) that is allowed in addition to the initial 5-second detection period for members to return to the group rather than being expelled. The timeout defaults to 5 seconds, so by default a member is not expelled until it has been absent for at least 10 seconds.

### 20.7.6.1 Increasing the cache size

If a member is absent for a period that is not long enough for it to be expelled from the group, it can reconnect and start participating in the group again by retrieving missed transactions from another member’s XCom message cache. However, if the transactions that happened during the member's absence have been deleted from the other members’ XCom message caches because their maximum size limit was reached, the member cannot reconnect in this way.

Group Replication's Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is currently unreachable is removed from the message cache. This warning message is logged on all the active group members (only once for each unreachable member). Although the group members cannot know for sure what message was the last message seen by the unreachable member, the warning message indicates that the cache size might not be sufficient to support your chosen waiting period before a member is expelled.

In this situation, consider increasing the `group_replication_message_cache_size` limit with reference to the expected volume of messages in the time period specified by the `group_replication_member_expel_timeout` system variable plus the 5-second detection period, so that the cache contains all the missed messages required for members to return successfully. You can also consider increasing the cache size limit temporarily if you expect a member to become unreachable for an unusual period of time.

### 20.7.6.2 Reducing the cache size

The minimum setting for the XCom message cache size in MySQL 8.4 is 128 MB, which enables deployment on a host that has a restricted amount of available memory. Having a very low `group_replication_message_cache_size` setting is not recommended if the host is on an unstable network, because a smaller message cache makes it harder for group members to reconnect after a transient loss of connectivity.

If a reconnecting member cannot retrieve all the messages it needs from the XCom message cache, the member must leave the group and rejoin it, in order to retrieve the missing transactions from another member's binary log using distributed recovery. A member that has left a group makes three auto-rejoin attempts by default, so the process of rejoining the group can still take place without operator intervention. However, rejoining using distributed recovery is a significantly longer and more complex process than retrieving messages from an XCom message cache, so the member takes longer to become available and the performance of the group can be impacted. On a stable network, which minimizes the frequency and duration of transient losses of connectivity for members, the frequency of this occurrence should also be minimized, so the group might be able to tolerate a smaller XCom message cache size without a significant impact on its performance.

If you are considering reducing the cache size limit, you can query the Performance Schema table `memory_summary_global_by_event_name` using the following statement:

```sql
SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/group_rpl/GCS_XCom::xcom_cache';
```

This returns memory usage statistics for the message cache, including the current number of cached entries and current size of the cache. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. XCom might temporarily exceed the cache size limit while this removal process is ongoing.

### 20.7.7 Responses to Failure Detection and Network Partitioning

Group Replication's failure detection mechanism is designed to identify group members that are no longer communicating with the group, and expel them as and when it seems likely that they have
Responses to Failure Detection and Network Partitioning

Failed. Having a failure detection mechanism increases the chance that the group contains a majority of correctly working members, and that requests from clients are therefore processed correctly.

Normally, all group members regularly exchange messages with all other group members. If a group member does not receive any messages from a particular fellow member for 5 seconds, when this detection period ends, it creates a suspicion of the fellow member. When a suspicion times out, the suspected member is assumed to have failed, and is expelled from the group. An expelled member is removed from the membership list seen by the other members, but it does not know that it has been expelled from the group, so it sees itself as online and the other members as unreachable. If the member has not in fact failed (for example, because it was just disconnected due to a temporary network issue) and it is able to resume communication with the other members, it receives a view containing the information that it has been expelled from the group.

The responses of group members, including the failed member itself, to these situations can be configured at a number of points in the process. By default, the following behaviors happen if a member is suspected of having failed:

1. In MySQL 8.4, when a suspicion is created, a waiting period of 5 seconds is added before the suspicion times out and the suspected member is liable for expulsion.

2. If an expelled member resumes communication and realises that it was expelled, it automatically makes three attempts to rejoin the group (with 5 minutes between each attempt); if this auto-rejoin procedure does not work, it then stops trying to rejoin the group.

3. When an expelled member is not trying to rejoin the group, it switches to super-read-only mode and awaits operator attention.

You can use the Group Replication configuration options described in this section to change these behaviors either permanently or temporarily, to suit your system's requirements and your priorities. If you are experiencing unnecessary expulsions caused by slower networks or machines, networks with a high rate of unexpected transient outages, or planned network outages, consider increasing the expel timeout and auto-rejoin attempts. While a member is undergoing any of the default behaviors described previously, although it does not accept writes, reads can still be performed if the member is still communicating with clients, with an increasing likelihood of stale reads over time. If avoiding stale reads is a higher priority for you than avoiding operator intervention, consider reducing the expel timeout and auto-rejoin attempts or setting them to zero.

Members that have not failed might lose contact with part, but not all, of the replication group due to a network partition. For example, in a group of 5 servers (S1, S2, S3, S4, S5), if there is a disconnection between (S1, S2) and (S3, S4, S5) there is a network partition. The first group (S1, S2) is now in a minority because it cannot contact more than half of the group. Any transactions that are processed by the members in the minority group are blocked, because the majority of the group is unreachable, therefore the group cannot achieve quorum. For a detailed description of this scenario, see Section 20.7.8, “Handling a Network Partition and Loss of Quorum”. In this situation, the default behavior is for the members in both the minority and the majority to remain in the group, continue to accept transactions (although they are blocked on the members in the minority), and wait for operator intervention. This behavior is also configurable.

Note that where group members are at an older MySQL Server release that does not support a relevant setting, or at a release with a different default, they act towards themselves and other group members according to the default behaviors stated above. For example, a member that does not support the group_replication_member_expel_timeout system variable expels other members as soon as an expired suspicion is detected, and this expulsion is accepted by other members even if they support the system variable and have a longer timeout set.

**20.7.7.1 Expel Timeout**

You can use the group_replication_member_expel_timeout system variable to allow additional time between the creation of a suspicion and the expulsion of the suspect member. A suspicion is created when one server does not receive messages from another server, as explained in Section 20.1.4.2, “Failure Detection”.

3629
Responses to Failure Detection and Network Partitioning

There is an initial 5-second detection period before a Group Replication group member creates a suspicion of another member (or of itself). A group member is then expelled when another member's suspicion of it (or its own suspicion of itself) times out. A further short period of time might elapse after that before the expelling mechanism detects and implements the expulsion. `group_replication_member_expel_timeout` specifies the period of time in seconds, called the expel timeout, that a group member waits between creating a suspicion, and expelling the suspected member. Suspect members are listed as `UNREACHABLE` during this waiting period, but are not removed from the group's membership list.

- If a suspect member becomes active again before the suspicion times out at the end of the waiting period, the member applies all the messages that were buffered by the remaining group members in XCom's message cache and enters `ONLINE` state, without operator intervention. In this situation, the member is considered by the group as the same incarnation.

- If a suspect member becomes active only after the suspicion times out and is able to resume communications, it receives a view where it is expelled and at that point realises it was expelled. You can use `group_replication_autorejoin_tries` to make the member try to rejoin the group automatically at this point. This feature is active by default in MySQL 8.4, and the member makes three auto-rejoin attempts. If the auto-rejoin procedure does not succeed or is not attempted, the expelled member then follows the exit action specified by `group_replication_exit_state_action`.

The waiting period before expelling a member only applies to members that have previously been active in the group. Non-members that were never active in the group do not get this waiting period and are removed after the initial detection period because they took too long to join.

If `group_replication_member_expel_timeout` is set to 0, there is no waiting period, and a suspected member is liable for expulsion immediately after the initial 5-second detection period ends. The default is 5, meaning that a suspected member is liable for expulsion 5 seconds after the 5-second detection period has expired. It is not mandatory for all members of a group to have the same setting for `group_replication_member_expel_timeout`, but it is recommended in order to avoid unexpected expulsions. Any member can create a suspicion of any other member, including itself, so the effective expel timeout is that of the member with the lowest setting.

Consider increasing the value of `group_replication_member_expel_timeout` from the default in the following scenarios:

- The network is slow and the default 5 or 10 seconds before expulsion is not long enough for group members to always exchange at least one message.

- The network sometimes has transient outages and you want to avoid unnecessary expulsions and primary member changes at these times.

- The network is not under your direct control and you want to minimize the need for operator intervention.

- A temporary network outage is expected and you do not want some or all of the members to be expelled due to this.

- An individual machine is experiencing a slowdown and you do not want it to be expelled from the group.

You can specify an expel timeout up to a maximum of 3600 seconds (1 hour). It is important to ensure that XCom's message cache is sufficiently large to contain the expected volume of messages in your specified time period, plus the initial 5-second detection period, otherwise members cannot reconnect. You can adjust the cache size limit using the `group_replication_message_cache_size` system variable. For more information, see Section 20.7.6, “XCom Cache Management”.

If any members in a group are currently under suspicion, the group membership cannot be reconfigured (by adding or removing members or electing a new leader). If group membership changes need to be implemented while one or more members are under suspicion, and you want the suspect
members to remain in the group, take any actions required to make the members active again, if that is possible. If you cannot make the members active again and you want them to be expelled from the group, you can force the suspicions to time out immediately. Do this by changing the value of `group_replication_member_expel_timeout` on any active members to a value lower than the time that has already elapsed since the suspicions were created. The suspect members then become liable for expulsion immediately.

If a replication group member stops unexpectedly and is immediately restarted (for example, because it was started with `mysqld_safe`), it automatically attempts to rejoin the group if `group_replication_start_on_boot=on` is set. In this situation, it is possible for the restart and rejoin attempt to take place before the member's previous incarnation has been expelled from the group, in which case the member cannot rejoin. Group Replication automatically uses a Group Communication System (GCS) feature to retry the rejoin attempt for the member 10 times, with a 5-second interval between each retry. This should cover most cases and allow enough time for the previous incarnation to be expelled from the group, letting the member rejoin. Note that if the `group_replication_member_expel_timeout` system variable is set to specify a longer waiting period before the member is expelled, the automatic rejoin attempts might still not succeed.

For alternative mitigation strategies to avoid unnecessary expulsions where the `group_replication_member_expel_timeout` system variable is not available, see Section 20.3.2, “Group Replication Limitations”.

### 20.7.7.2 Unreachable Majority Timeout

By default, members that find themselves in a minority due to a network partition do not automatically leave the group. You can use the system variable `group_replication_unreachable_majority_timeout` to set a number of seconds for a member to wait after losing contact with the majority of group members, and then exit the group. Setting a timeout means you do not need to pro-actively monitor for servers that are in a minority group after a network partition, and you can avoid the possibility of creating a split-brain situation (with two versions of the group membership) due to inappropriate intervention.

When the timeout specified by `group_replication_unreachable_majority_timeout` elapses, all pending transactions that have been processed by the member and the others in the minority group are rolled back, and the servers in that group move to the `ERROR` state. You can use the `group_replication_autorejoin_tries` system variable to force the member to try to rejoin the group automatically at this point. This feature is active by default; the member makes three auto-rejoin attempts. If the auto-rejoin procedure does not succeed or is not attempted, the minority member then follows the exit action specified by `group_replication_exit_state_action`.

Consider the following points when deciding whether or not to set an unreachable majority timeout:

- In a symmetric group, for example a group with two or four servers, if both partitions contain an equal number of servers, both groups consider themselves to be in a minority and enter the `ERROR` state. In this situation, the group has no functional partition.

- While a minority group exists, any transactions processed by the minority group are accepted, but blocked because the minority servers cannot reach quorum, until either `STOP GROUP_REPLICATION` is issued on those servers or the unreachable majority timeout is reached.

- If you do not set an unreachable majority timeout, the servers in the minority group never enter the `ERROR` state automatically, and you must stop them manually.

- Setting an unreachable majority timeout has no effect if it is set on the servers in the minority group after the loss of majority has been detected.

If you do not use the `group_replication_unreachable_majority_timeout` system variable, the process for operator invention in the event of a network partition is described in Section 20.7.8, “Handling a Network Partition and Loss of Quorum”. The process involves checking which servers are functioning and forcing a new group membership if necessary.
20.7.7.3 Auto-Rejoin

The `group_replication_autorejoin_tries` system variable makes a member that has been expelled or reached its unreachable majority timeout try to rejoin the group automatically. The default (3), means that the member automatically makes 3 attempts to rejoin the group, with 5 minutes between each attempt.

When auto-rejoin is not activated, a member accepts its expulsion as soon as it resumes communication, and proceeds to the action specified by the `group_replication_exit_state_action` system variable. After this, manual intervention is needed to bring the member back into the group. Using the auto-rejoin feature is appropriate if you can tolerate the possibility of stale reads and want to minimize the need for manual intervention, especially where transient network issues fairly often result in the expulsion of members.

With auto-rejoin, when the member's expulsion or unreachable majority timeout is reached, it makes an attempt to rejoin (using the current plugin option values), then continues to make further auto-rejoin attempts up to the specified number of tries. After an unsuccessful auto-rejoin attempt, the member waits 5 minutes before the next try. The auto-rejoin attempts and the time between them are called the auto-rejoin procedure. If the specified number of tries is exhausted without the member rejoining or being stopped, the member proceeds to the action specified by the `group_replication_exit_state_action` system variable.

During and between auto-rejoin attempts, a member remains in super read only mode and displays an `ERROR` state on its view of the replication group. During this time, the member does not accept writes. However, reads can still be made on the member, with an increasing likelihood of stale reads over time. If you do want to intervene to take the member offline during the auto-rejoin procedure, the member can be stopped manually at any time by using a `STOP GROUP_REPLICATION` statement or shutting down the server. If you cannot tolerate the possibility of stale reads for any period of time, set the `group_replication_autorejoin_tries` system variable to 0.

You can monitor the auto-rejoin procedure using the Performance Schema. While an auto-rejoin procedure is taking place, the Performance Schema table `events_stages_current` shows the event "Undergoing auto-rejoin procedure", with the number of retries that have been attempted so far during this instance of the procedure (in the `WORK_COMPLETED` field). The `events_stages_summary_global_by_event_name` table shows the number of times the server instance has initiated the auto-rejoin procedure (in the `COUNT_STAR` field). The `events_stages_history_long` table shows the time each of these auto-rejoin procedures was completed (in the `TIMER_END` field). While a member is rejoining a replication group, its status can be displayed as `OFFLINE` or `ERROR` before the group completes the compatibility checks and accepts it as a member. When the member is catching up with the group's transactions, its status is `RECOVERING`.

20.7.7.4 Exit Action

The `group_replication_exit_state_action` system variable specifies what Group Replication does when the member leaves the group unintentionally due to an error or problem, and either fails to auto-rejoin or does not try. Note that in the case of an expelled member, the member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

In order of impact, the exit actions are as follows:

1. If `READ_ONLY` is the exit action, the instance switches MySQL to super read only mode by setting the system variable `super_read_only` to `ON`. When the member is in super read only mode, clients cannot make any updates, even if they have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). However, clients can still read data, and because updates are no longer being made, there is a probability of stale reads which increases over time. With this setting, you therefore need to pro-actively monitor the servers for failures. This exit action is the default; after it is taken, the member's status is shown as `ERROR` in the view of the group.

2. If `OFFLINE_MODE` is the exit action, the instance switches MySQL to offline mode by setting the system variable `offline_mode` to `ON`. When the member is in offline mode, connected client
users are disconnected on their next request and connections are no longer accepted, with the exception of client users that have the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege). Group Replication also sets the system variable super_read_only to ON, so clients cannot make any updates, even if they have connected with the CONNECTION_ADMIN or SUPER privilege. This exit action prevents both updates and stale reads (with the exception of reads by client users with the stated privileges), and enables proxy tools such as MySQL Router to recognize that the server is unavailable and redirect client connections. It also leaves the instance running so that an administrator can attempt to resolve the issue without shutting down MySQL. After this exit action is taken, the member's status is displayed as ERROR in the view of the group (not OFFLINE, which means a member has Group Replication functionality available but does not currently belong to a group).

3. If ABORT_SERVER is the exit action, the instance shuts down MySQL. Instructing the member to shut itself down prevents all stale reads and client updates, but it means that the MySQL Server instance is unavailable and must be restarted, even if the issue could have been resolved without that step. After this exit action is taken, the member is removed from the listing of servers in the view of the group.

Bear in mind that operator intervention is required whatever exit action is set, as an ex-member that has exhausted its auto-rejoin attempts (or never had any) and has been expelled from the group is not allowed to rejoin without a restart of Group Replication. The exit action only influences whether or not clients can still read data on the server that was unable to rejoin the group, and whether or not the server stays running.

---

Important

If a failure occurs before the member has successfully joined the group, the exit action specified by group_replication_exit_state_action is not taken. This is the case if there is a failure during the local configuration check, or a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the super_read_only system variable is left with its original value, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that super_read_only=ON is set in the server's configuration file at startup, which Group Replication changes to OFF on primary members after it has been started successfully. This safeguard is particularly important when the server is configured to start Group Replication on server boot (group_replication_start_on_boot=ON), but it is also useful when Group Replication is started manually using a START GROUP_REPLICATION statement.

If a failure occurs after the member has successfully joined the group, the specified exit action is taken. This is the case in the following situations:

1. **Applier error** - There is an error in the replication applier. This issue is not recoverable.

2. **Distributed recovery not possible** - There is an issue that means Group Replication's distributed recovery process (which uses remote cloning operations and state transfer from the binary log) cannot be completed. Group Replication retries distributed recovery automatically where this makes sense, but stops if there are no more options to complete the process. For details, see Section 20.5.4.4, “Fault Tolerance for Distributed Recovery”.

3. **Group configuration change error** - An error occurred during a group-wide configuration change carried out using a function, as described in Section 20.5.1, “Configuring an Online Group”.

4. **Primary election error** - An error occurred during election of a new primary member for a group in single-primary mode, as described in Section 20.1.3.1, “Single-Primary Mode”.

5. **Unreachable majority timeout** - The member has lost contact with a majority of the group members so is in a minority, and a timeout that was set by the group_replication_unreachable_majority_timeout system variable has expired.
6. **Member expelled from group** - A suspicion has been raised on the member, and any timeout set by the `group_replication_member_expel_timeout` system variable has expired, and the member has resumed communication with the group and found that it has been expelled.

7. **Out of auto-rejoin attempts** - The `group_replication_autorejoin_tries` system variable was set to specify a number of auto-rejoin attempts after a loss of majority or expulsion, and the member completed this number of attempts without success.

The following table summarizes the failure scenarios and actions in each case:

<table>
<thead>
<tr>
<th>Failure situation</th>
<th>Group Replication started with <code>START GROUP_REPLICATION</code></th>
<th>Group Replication started with <code>group_replication_start_on_boot=ON</code></th>
</tr>
</thead>

### 20.7.8 Handling a Network Partition and Loss of Quorum

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example, in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.
Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

For a group in single-primary mode, the primary might have transactions that are not yet present on other members at the time of the network partition. If you are considering excluding the primary from the new group, be aware that such transactions might be lost. A member with extra transactions cannot rejoin the group, and the attempt results in an error with the message `This member has more executed transactions than those present in the group`. Set the `group_replication_unreachable_majority_timeout` system variable for the group members to avoid this situation.

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

### Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status `UNREACHABLE` for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.
Handling a Network Partition and Loss of Quorum

To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, let's assume that there is a group with these 5 servers in it:

- Server s1 with member identifier 199b2df7-4aaf-11e6-bb16-28b2bd168d07
- Server s2 with member identifier 199bb88e-4aaf-11e6-babe-28b2bd168d07
- Server s3 with member identifier 1999b9fb-4aaf-11e6-bb54-28b2bd168d07
- Server s4 with member identifier 19ab72fc-4aaf-11e6-bb51-28b2bd168d07
- Server s5 with member identifier 19b33846-4aaf-11e6-ba81-28b2bd168d07

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its replication_group_members performance schema table. For example:
Handling a Network Partition and Loss of Quorum

mysql> SELECT MEMBER_ID, MEMBER_STATE, MEMBER_ROLE FROM performance_schema.replication_group_members;
+--------------------------------------+--------------+-------------+
| MEMBER_ID                            | MEMBER_STATE | MEMBER_ROLE |
+--------------------------------------+--------------+-------------+
| 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | ONLINE       | SECONDARY   |
| 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | ONLINE       | PRIMARY     |
| 199bb88e-4aaf-11e6-babe-28b2bd168d07 | ONLINE       | SECONDARY   |
| 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | ONLINE       | SECONDARY   |
| 19b33846-4aaf-11e6-ba81-28b2bd168d07 | ONLINE       | SECONDARY   |
+--------------------------------------+--------------+-------------+

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several others members are not. In fact, as seen below they are marked as **UNREACHABLE**. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
+--------------------------------------+--------------+
| MEMBER_ID                            | MEMBER_STATE |
+--------------------------------------+--------------+
| 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | UNREACHABLE  |
| 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | ONLINE       |
| 199bb88e-4aaf-11e6-babe-28b2bd168d07 | ONLINE       |
| 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | UNREACHABLE  |
| 19b33846-4aaf-11e6-ba81-28b2bd168d07 | UNREACHABLE  |
+--------------------------------------+--------------+
```

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

**Unblocking a Partition**

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could choose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.
Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

Warning

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It must be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

When forcing a new membership configuration, make sure that any servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shut down and if they are not, shut them down before proceeding.
Warning
For a group in single-primary mode, the primary might have transactions that are not yet present on other members at the time of the network partition. If you are considering excluding the primary from the new group, be aware that such transactions might be lost. A member with extra transactions cannot rejoin the group, and the attempt results in an error with the message This member has more executed transactions than those present in the group. Set the group_replication_unreachable_majority_timeout system variable for the group members to avoid this situation.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```
mysql> SELECT MEMBER_ID,MEMBER_STATE FROM performance_schema.replication_group_members;
+--------------------------------------+--------------+
| MEMBER_ID                            | MEMBER_STATE |
+--------------------------------------+--------------+
| 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | UNREACHABLE  |
| 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | ONLINE       |
| 199bb88e-4aaf-11e6-babe-28b2bd168d07 | ONLINE       |
| 1abb72fc-4aaf-11e6-bb51-28b2bd168d07 | UNREACHABLE  |
| 19b33846-4aaf-11e6-ba81-28b2bd168d07 | UNREACHABLE  |
+--------------------------------------+--------------+
```

The first thing to do is to check what is the local address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
```

Once you know the group communication addresses of s1 (127.0.0.1:10000) and s2 (127.0.0.1:10001), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
```

This unblocks the group by forcing a different configuration. Check replication_group_members on both s1 and s2 to verify the group membership after this change. First on s1.

```
mysql> SELECT MEMBER_ID,MEMBER_STATE FROM performance_schema.replication_group_members;
+--------------------------------------+--------------+
| MEMBER_ID                            | MEMBER_STATE |
+--------------------------------------+--------------+
| b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | ONLINE       |
| b60907e7-4ab6-11e6-afb7-28b2bd168d07 | ONLINE       |
+--------------------------------------+--------------+
```

And then on s2.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

After you have used the group_replication_force_members system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. group_replication_force_members must be empty in order to issue a START GROUP_REPLICATION statement.

20.7.9 Monitoring Group Replication Memory Usage with Performance Schema Memory Instrumentation
The MySQL Performance Schema provides instrumentation for performance monitoring of Group Replication memory usage. To view the available Group Replication instrumentation, issue the following query:

```
mysql> SELECT NAME, ENABLED FROM performance_schema.setup_instruments
       WHERE NAME LIKE 'memory/group_rpl/%';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
</tr>
</thead>
<tbody>
<tr>
<td>memory/group_rpl/write_set_encoded</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/certification_data</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/certification_data_gc</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/certification_info</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/transaction_data</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/sql_service_command_data</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/mysql_thread_queued_task</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/message_service_queue</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/message_service_received_message</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/group_member_info</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/consistent_members_that_must_prepare_transaction</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/consistent_transactions</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/consistent_transactions_prepared</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/consistent_transactions_waiting</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/consistent_transactions_delayed_view_change</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/GCS_XCom::xcom_cache</td>
<td>YES</td>
</tr>
<tr>
<td>memory/group_rpl/Gcs_message_data::m_buffer</td>
<td>YES</td>
</tr>
</tbody>
</table>

For more information on Performance Schema’s memory instrumentation and events, see Section 29.12.20.10, “Memory Summary Tables”.

Performance Schema Group Replication instruments memory allocation for Group Replication. The `memory/group_rpl/` Performance Schema instrumentation contains the following instruments:

- **write_set_encoded**: Memory allocated to encode the write set before it is broadcast to the group members.
- **Gcs_message_data::m_buffer**: Memory allocated for the transaction data payload sent to the network.
- **certification_data**: Memory allocated for certification of incoming transactions.
- **certification_data_gc**: Memory allocated for the GTID_EXECUTED sent by each member for garbage collection.
- **certification_info**: Memory allocated for storage of certification information allocated to resolve conflicts between concurrent transactions.
- **transaction_data**: Memory allocated for incoming transactions queued for the plugin pipeline.
- **message_service_received_message**: Memory allocated to receiving messages from Group Replication delivery message service.
- **sql_service_command_data**: Memory allocated for processing the queue of internal SQL service commands.
- **mysql_thread_queued_task**: Memory allocated when a MySQL-thread dependent task is added to the processing queue.
- **message_service_queue**: Memory allocated for queued messages of the Group Replication delivery message service.
- **GCS_XCom::xcom_cache**: Memory allocated to XCOM ache for messaging and metadata exchanged between group members as part of the consensus protocol.
- **consistent_members_that_must_prepare_transaction**: Memory allocated to hold list of members preparing transaction for Group Replication transaction consistency guarantees.
Monitoring Group Replication Memory Usage with Performance Schema Memory Instrumentation

• **consistent_transactions**: Memory allocated to hold transaction and list of members that must prepare that transaction for Group Replication transaction consistency guarantees.

• **consistent_transactions_prepared**: Memory allocated to hold list of transaction's info prepared for the Group Replication Transaction Consistency Guarantees.

• **consistent_transactions_waiting**: Memory allocated to hold information on a list of transactions while preceding prepared transactions with consistency of AFTER and BEFORE_AND_AFTER are processed.

• **consistent_transactions_delayed_view_change**: Memory allocated to hold list of view change events (view_change_log_event) delayed by prepared consistent transactions waiting for prepare acknowledgement.

• **group_member_info**: Memory allocated to hold the group member properties. Properties such as hostname, port, member weight and role, and so on.

The following instruments in the `memory/sql/` grouping are also used to monitor Group Replication memory:

• **Log_event**: Memory allocated for encoding transaction data into the binary log format; this is the same format in which Group Replication transmits data.

• **write_set_extraction**: Memory allocated to the transaction's generated write set before it is committed.

• **Gtid_set::to_string**: Memory allocated to stored the string representation of a GTID set.

• **Gtid_set::Interval_chunk**: Memory allocated to store the GTID object.

### 20.7.9.1 Enabling or Disabling Group Replication Instrumentation

To enable all the Group Replication instrumentation from the command line, run the following in the SQL client of your choice:

```sql
UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
WHERE NAME LIKE 'memory/group_rpl/%';
```

To disable all the Group Replication instrumentation from the command line, run the following in the SQL client of your choice:

```sql
UPDATE performance_schema.setup_instruments SET ENABLED = 'NO'
WHERE NAME LIKE 'memory/group_rpl/%';
```

To enable all the Group Replication instrumentation at server startup, add the following to your option file:

```ini
[mysqld]
performance-schema-instrument='memory/group_rpl/%=ON'
```

To disable all the Group Replication instrumentation at server startup, add the following to your option file:

```ini
[mysqld]
performance-schema-instrument='memory/group_rpl/%=OFF'
```

To enable or disable individual instruments in that group, replace the wildcard (%) with the full name of the instrument.

For more information, see Section 29.3, “Performance Schema Startup Configuration” and Section 29.4, “Performance Schema Runtime Configuration”.

3641
20.7.9.2 Example Queries

This section describes sample queries using the instruments and events for monitoring Group Replication memory usage. The queries retrieve data from the `memory_summary_global_by_event_name` table.

The memory data can be queried for individual events, for example:

```
SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME = 'memory/group_rpl/write_set_encoded'
```

```
*************************** 1. row ***************************
EVENT_NAME: memory/group_rpl/write_set_encoded
COUNT_ALLOC: 1
COUNT_FREE: 0
SUM_NUMBER_OF_BYTES_ALLOC: 45
SUM_NUMBER_OF_BYTES_FREE: 0
LOW_COUNT_USED: 0
CURRENT_COUNT_USED: 1
HIGH_COUNT_USED: 1
LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 45
HIGH_NUMBER_OF_BYTES_USED: 45
```

See Section 29.12.20.10, “Memory Summary Tables” for more information on the columns.

You can also define queries which sum various events to provide overviews of specific areas of memory usage.

The following examples are described:

- Memory Used to Capture Transactions
- Memory Used to Broadcast Transactions
- Total Memory Used in Group Replication
- Memory Used in Certification
- Memory Used in Certification
- Memory Used in Replication Pipeline
- Memory Used in Consistency
- Memory Used in Delivery Message Service
- Memory Used to Broadcast and Receive Transactions

Memory Used to Capture Transactions

The memory allocated to capture user transactions is a sum of the `write_set_encoded`, `write_set_extraction`, and `Log_event` event's values. For example:

```
mysql> SELECT * FROM (SELECT (CASE
    WHEN EVENT_NAME LIKE 'memory/group_rpl/write_set_encoded'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/sql/write_set_extraction'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/sql/Log_event'
    THEN 'memory/group_rpl/memory_gr'
    ELSE 'memory_gr_rest'
    END) AS EVENT_NAME, SUM(COUNT_ALLOC), SUM(COUNT_FREE),
    SUM(SUM_NUMBER_OF_BYTES_ALLOC),
    SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
    SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
    SUM(HIGH_NUMBER_OF_BYTES_USED)
FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME = 'memory/group_rpl/write_set_encoded'
GROUP BY EVENT_NAME)
```

3642
Monitoring Group Replication Memory Usage with Performance Schema Memory Instrumentation

```
SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
SUM(HIGH_NUMBER_OF_BYTES_USED)
FROM performance_schema.memory_summary_global_by_event_name
GROUP BY (CASE
    WHEN EVENT_NAME LIKE 'memory/group_rpl/write_set_encoded'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/sql/write_set_extraction'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/sql/Log_event'
    THEN 'memory/group_rpl/memory_gr'
    ELSE 'memory_gr_rest'
END)
WHERE f.EVENT_NAME != 'memory_gr_rest'

*************************** 1. row ***************************
EVENT_NAME: memory/group_rpl/memory_gr
SUM(COUNT_ALLOC): 127
SUM(COUNT_FREE): 117
SUM(SUM_NUMBER_OF_BYTES_ALLOC): 54808
SUM(SUM_NUMBER_OF_BYTES_FREE): 52051
SUM(LOW_COUNT_USED): 0
SUM(CURRENT_COUNT_USED): 10
SUM(HIGH_COUNT_USED): 35
SUM(LOW_NUMBER_OF_BYTES_USED): 0
SUM(CURRENT_NUMBER_OF_BYTES_USED): 2757
SUM(HIGH_NUMBER_OF_BYTES_USED): 15630
```

Memory Used to Broadcast Transactions

The memory allocated to broadcast transactions is a sum of the `Gcs_message_data::m_buffer`, `transaction_data`, and `GCS_XCom::xcom_cache` event values. For example:

```
mysql> SELECT * FROM {
    SELECT (CASE
        WHEN EVENT_NAME =  'memory/group_rpl/Gcs_message_data::m_buffer'
        THEN 'memory/group_rpl/memory_gr'
        WHEN EVENT_NAME = 'memory/group_rpl/GCS_XCom::xcom_cache'
        THEN 'memory/group_rpl/memory_gr'
        WHEN EVENT_NAME = 'memory/group_rpl/transaction_data'
        THEN 'memory/group_rpl/memory_gr'
        ELSE 'memory_gr_rest'
    END) AS EVENT_NAME, SUM(COUNT_ALLOC), SUM(COUNT_FREE),
    SUM(SUM_NUMBER_OF_BYTES_ALLOC),
    SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
    SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
    SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
    SUM(HIGH_NUMBER_OF_BYTES_USED)
FROM performance_schema.memory_summary_global_by_event_name
GROUP BY (CASE
    WHEN EVENT_NAME =  'memory/group_rpl/Gcs_message_data::m_buffer'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/group_rpl/GCS_XCom::xcom_cache'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/group_rpl/transaction_data'
    THEN 'memory/group_rpl/memory_gr'
    ELSE 'memory_gr_rest'
END)
WHERE f.EVENT_NAME != 'memory_gr_rest'

*************************** 1. row ***************************
EVENT_NAME: memory/group_rpl/memory_gr
SUM(COUNT_ALLOC): 84
SUM(COUNT_FREE): 31
SUM(SUM_NUMBER_OF_BYTES_ALLOC): 1072324
SUM(SUM_NUMBER_OF_BYTES_FREE): 7149
SUM(LOW_COUNT_USED): 0
SUM(CURRENT_COUNT_USED): 53
SUM(HIGH_COUNT_USED): 59
SUM(LOW_NUMBER_OF_BYTES_USED): 0
SUM(CURRENT_NUMBER_OF_BYTES_USED): 1065175
```
Total Memory Used in Group Replication

The memory allocation to sending and receiving transactions, certification, and all other major processes. It is calculated by querying all the events of the `memory/group_rpl/` group. For example:

```sql
mysql> SELECT * FROM (SELECT (CASE WHEN EVENT_NAME LIKE 'memory/group_rpl/%' THEN 'memory/group_rpl/memory_gr' ELSE 'memory_gr_rest' END) AS EVENT_NAME, SUM(COUNT_ALLOC), SUM(COUNT_FREE), SUM(SUM_NUMBER_OF_BYTES_ALLOC), SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED), SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED), SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED), SUM(HIGH_NUMBER_OF_BYTES_USED) FROM performance_schema.memory_summary_global_by_event_name GROUP BY (CASE WHEN EVENT_NAME LIKE 'memory/group_rpl/%' THEN 'memory/group_rpl/memory_gr' ELSE 'memory_gr_rest' END)) f WHERE f.EVENT_NAME != 'memory_gr_rest'\G
*************************** 1. row ***************************
EVENT_NAME: memory/group_rpl/memory_gr
SUM(COUNT_ALLOC): 190
SUM(COUNT_FREE): 127
SUM(SUM_NUMBER_OF_BYTES_ALLOC): 1096370
SUM(SUM_NUMBER_OF_BYTES_FREE): 28675
SUM(LOW_COUNT_USED): 0
SUM(CURRENT_COUNT_USED): 63
SUM(HIGH_COUNT_USED): 77
SUM(LOW_NUMBER_OF_BYTES_USED): 0
SUM(CURRENT_NUMBER_OF_BYTES_USED): 1067695
SUM(HIGH_NUMBER_OF_BYTES_USED): 1069255
```

Memory Used in Certification

The memory allocation in the certification process is a sum of the `certification_data`, `certification_data_gc`, and `certification_info` event values. For example:

```sql
mysql> SELECT * FROM (SELECT (CASE WHEN EVENT_NAME = 'memory/group_rpl/certification_data' THEN 'memory/group_rpl/certification' WHEN EVENT_NAME = 'memory/group_rpl/certification_data_gc' THEN 'memory/group_rpl/certification' WHEN EVENT_NAME = 'memory/group_rpl/certification_info' THEN 'memory/group_rpl/certification' ELSE 'memory_gr_rest' END) AS EVENT_NAME, SUM(COUNT_ALLOC), SUM(COUNT_FREE), SUM(SUM_NUMBER_OF_BYTES_ALLOC), SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED), SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED), SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED), SUM(HIGH_NUMBER_OF_BYTES_USED) FROM performance_schema.memory_summary_global_by_event_name GROUP BY (CASE WHEN EVENT_NAME = 'memory/group_rpl/certification_data' THEN 'memory/group_rpl/certification' WHEN EVENT_NAME = 'memory/group_rpl/certification_data_gc' THEN 'memory/group_rpl/certification' WHEN EVENT_NAME = 'memory/group_rpl/certification_info' THEN 'memory/group_rpl/certification' ELSE 'memory_gr_rest' END)) f WHERE f.EVENT_NAME != 'memory_gr_rest'\G
```

SUM(HIGH_NUMBER_OF_BYTES_USED): 1065809
Memory Used in Replication Pipeline

The memory allocation of the replication pipeline is the sum of the `certification_data` and `transaction_data` event values. For example:

```sql
mysql> SELECT * FROM (  
    SELECT  
    (CASE  
        WHEN EVENT_NAME LIKE 'memory/group_rpl/certification_data'  
        THEN 'memory/group_rpl/pipeline'  
        WHEN EVENT_NAME LIKE 'memory/group_rpl/transaction_data'  
        THEN 'memory/group_rpl/pipeline'  
        ELSE 'memory_gr_rest'  
    END) AS EVENT_NAME,

Memory Used in Consistency

The memory allocation for transaction consistency guarantees is the sum of the `consistent_members_that_must_prepare_transaction`, `consistent_transactions`, `consistent_transactions_prepared`, `consistent_transactions_waiting`, and `consistent_transactions_delayed_view_change` event values. For example:

```sql
mysql> SELECT * FROM (  
    SELECT  
    (CASE  
        WHEN EVENT_NAME LIKE 'memory/group_rpl/certification_data'  
        THEN 'memory/group_rpl/pipeline'  
        WHEN EVENT_NAME LIKE 'memory/group_rpl/transaction_data'  
        THEN 'memory/group_rpl/pipeline'  
        ELSE 'memory_gr_rest'  
    END) AS EVENT_NAME,  
    SUM(COUNT_ALLOC),  
    SUM(COUNT_FREE),  
    SUM(SUM_NUMBER_OF_BYTES_ALLOC),  
    SUM(SUM_NUMBER_OF_BYTES_FREE),  
    SUM(LOW_COUNT_USED),  
    SUM(CURRENT_COUNT_USED),  
    SUM(HIGH_COUNT_USED),  
    SUM(LOW_NUMBER_OF_BYTES_USED),  
    SUM(CURRENT_NUMBER_OF_BYTES_USED),  
    SUM(HIGH_NUMBER_OF_BYTES_USED)  
    FROM performance_schema.memory_summary_global_by_event_name  
    GROUP BY (CASE  
        WHEN EVENT_NAME LIKE 'memory/group_rpl/certification_data'  
        THEN 'memory/group_rpl/pipeline'  
        WHEN EVENT_NAME LIKE 'memory/group_rpl/transaction_data'  
        THEN 'memory/group_rpl/pipeline'  
        ELSE 'memory_gr_rest'  
    END)  
) f  
WHERE f.EVENT_NAME != 'memory_gr_rest'"G  
*************************** 1. row ***************************

SUM_NUMBER_OF_BYTES_FREE: 528
LOW_COUNT_USED: 0
CURRENT_COUNT_USED: 10
HIGH_COUNT_USED: 11
LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 936
HIGH_NUMBER_OF_BYTES_USED: 1024
```

**Memory Used in Delivery Message Service**

![Note]

This instrumentation applies only to data received, not data sent.

The memory allocation for the Group Replication delivery message service is the sum of the `message_service_received_message` and `message_service_queue` event values. For example:

```
mysql> SELECT * FROM (SELECT
(CASE
WHEN EVENT_NAME = 'memory/group_rpl/message_service_received_message'
THEN 'memory/group_rpl/message_service'
WHEN EVENT_NAME = 'memory/group_rpl/message_service_queue'
THEN 'memory/group_rpl/message_service'
ELSE 'memory_gr_rest'
END) AS EVENT_NAME, SUM(COUNT_ALLOC), SUM(COUNT_FREE),
SUM(SUM_NUMBER_OF_BYTES_ALLOC), SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LONG_COUNT_USED),
SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
SUM(HIGH_NUMBER_OF_BYTES_USED),
```
### Memory Used to Broadcast and Receive Transactions

The memory allocation for the broadcasting and receiving transactions to and from the network is the sum of the `wGcs_message_data::m_buffer` and `GCS_XCom::xcom_cache` event values. For example:

```sql
SELECT EVENT_NAME, SUM(COUNT_ALLOC), SUM(COUNT_FREE), SUM(SUM_NUMBER_OF_BYTES_ALLOC), SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED), SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED), SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED), SUM(HIGH_NUMBER_OF_BYTES_USED)
FROM performance_schema.memory_summary_global_by_event_name
GROUP BY (CASE
    WHEN EVENT_NAME = 'memory/group_rpl/Gcs_message_data::m_buffer'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/group_rpl/GCS_XCom::xcom_cache'
    THEN 'memory/group_rpl/memory_gr'
    ELSE 'memory_gr_rest'
END)
WHERE f.EVENT_NAME != 'memory_gr_rest';
```

<table>
<thead>

20.8 Upgrading Group Replication
This section explains how to upgrade a Group Replication setup. The basic process of upgrading members of a group is the same as upgrading stand-alone instances, see Chapter 3, Upgrading MySQL for the actual process of doing upgrade and types available. Choosing between an in-place or logical upgrade depends on the amount of data stored in the group. Usually an in-place upgrade is faster, and therefore is recommended. You should also consult Section 19.5.3, “Upgrading or Downgrading a Replication Topology”.

Note
Before MySQL 8.4, a server would not join a group if it was running a lower MySQL Server version than the lowest group member's version. For example, for a group with S1 (8.0.30), S2 (8.0.31), and S3 (8.0.32), the joining member needs to be 8.0.30 or higher. MySQL 8.4 allows all versions within the 8.4 series to join. For example, an 8.4.0 server could join a group consisting of S1 (8.4.1) and S2 (8.4.2).

While you are in the process of upgrading an online group, in order to maximize availability, you might need to have members with different MySQL Server versions running at the same time. Group Replication includes compatibility policies that enable you to safely combine members running different versions of MySQL in the same group during the upgrade procedure. Depending on your group, the effects of these policies might affect the order in which you should upgrade group members. For details, see Section 20.8.1, “Combining Different Member Versions in a Group”.

If your group can be taken fully offline see Section 20.8.2, “Group Replication Offline Upgrade”. If your group needs to remain online, as is common with production deployments, see Section 20.8.3, “Group Replication Online Upgrade” for the different approaches available for upgrading a group with minimal downtime.

20.8.1 Combining Different Member Versions in a Group

Group Replication is versioned according to the MySQL Server version that the Group Replication plugin was bundled with. For example, if a member is running MySQL 8.4.0 then that is the version of the Group Replication plugin. To check the version of MySQL Server on a group member issue:

```sql
SELECT member_host, member_port, member_version FROM performance_schema.replication_group_members;
```

<table>
<thead>
<tr>
<th>member_host</th>
<th>member_port</th>
<th>member_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>example.com</td>
<td>3306</td>
<td>8.4.0</td>
</tr>
</tbody>
</table>

For guidance on understanding the MySQL Server version and selecting a version, see Section 2.1.2, "Which MySQL Version and Distribution to Install".

For optimal compatibility and performance, all members of a group should run the same version of MySQL Server and therefore of Group Replication. However, while you are in the process of upgrading an online group, in order to maximize availability, you might need to have members with different MySQL Server versions running at the same time. Depending on the changes made between the versions of MySQL, you could encounter incompatibilities in this situation. For example, if a feature has been deprecated between major versions, then combining the versions in a group might cause members that rely on the deprecated feature to fail. Conversely, writing to a member running a newer MySQL version while there are read-write members in the group running an older MySQL version might cause issues on members that lack functions introduced in the newer release.

To prevent these issues, Group Replication includes compatibility policies that enable you to safely combine members running different versions of MySQL in the same group. A member applies these policies to decide whether to join the group normally, or join in read-only mode, or not join the group, depending on which choice results in the safe operation of the joining member and of the existing members of the group. In an upgrade scenario, each server must leave the group, be upgraded, and rejoin the group with its new server version. At this point the member applies the policies for its new server version, which might have changed from the policies it applied when it originally joined the group.
As the administrator, you can instruct any server to attempt to join any group by configuring the server appropriately and issuing a `START GROUP_REPLICATION` statement. A decision to join or not join the group, or to join the group in read-only mode, is made and implemented by the joining member itself after you attempt to add it to the group. The joining member receives information on the MySQL Server versions of the current group members, assesses its own compatibility with those members, and applies the policies used in its own MySQL Server version (not the policies used by the existing members) to decide whether it is compatible.

The compatibility policies that a joining member applies when attempting to join a group are as follows:

- A member joins a group normally if it is running the same MySQL Server version as the lowest version that the existing group members are running.

- A member joins a group but remains in read-only mode if it is running a higher MySQL Server version than the lowest version that the existing group members are running. This behavior only makes a difference when the group is running in multi-primary mode, because in a group that is running in single-primary mode, newly added members default to being read-only in any case.

Members take into account the entire major.minor.release version of the software when checking compatibility.

In a multi-primary mode group with members that use different MySQL Server versions, Group Replication automatically manages members' read-write and read-only status. If a member leaves the group, the members running the version that is now the lowest are automatically set to read-write mode. When you change a group that was running in single-primary mode to run in multi-primary mode, using the `group_replication_switch_to_multi_primary_mode()` function, Group Replication automatically sets members to the correct mode. Members are automatically placed in read-only mode if they are running a higher MySQL server version than the lowest version present in the group, and members running the lowest version are placed in read-write mode.

### 20.8.1.1 Member Versions During Upgrades

During an online upgrade procedure, if the group is in single-primary mode, all the servers that are not currently offline for upgrading function as they did before. The group elects a new primary whenever necessary, following the election policies described in Section 20.1.3.1, “Single-Primary Mode”. Note that if you require the primary to remain the same throughout (except when it is being upgraded itself), you must first upgrade all of the secondaries to a version higher than or equal to the target primary member version, then upgrade the primary last. The primary cannot remain as the primary unless it is running the lowest MySQL Server version in the group. After the primary has been upgraded, you can use the `group_replication_set_as_primary()` function to reappoint it as the primary.

If the group is in multi-primary mode, fewer online members are available to perform writes during the upgrade procedure, because upgraded members join in read-only mode after their upgrade. When all members have been upgraded to the same release, they all change back to read-write mode automatically.

To deal with a problem situation, for example if you have to roll back an upgrade to a previous major version or add extra capacity to a group in an emergency, it is possible to allow a member to join an online group from a version that otherwise couldn't. The deprecated Group Replication system variable `group_replication_allow_local_lower_version_join` can be used in such situations to override the normal compatibility policies.

**Important**

Setting `group_replication_allow_local_lower_version_join` to ON does not make the new member compatible with the group; doing this allows it to join the group without any safeguards against incompatible behaviors by the existing members. This must therefore only be used carefully in specific situations, and you must take additional precautions to avoid the new member failing due to normal group activity. See the description of this variable for more information.
You should be aware that `group_replication_allow_local_lower_version_join` is deprecated; expect it to be removed in a future version of MySQL. Setting it generates an `ER_WARN_DEPRECATED_SYNTAX_NO_REPLACEMENT` level warning. No replacement is planned.

### 20.8.1.2 Group Replication Communication Protocol Version

A replication group uses a Group Replication communication protocol version that differs from the MySQL Server version of the members. To check the group's communication protocol version, issue the following statement on any member:

```sql
SELECT @@version, group_replication_get_communication_protocol();
+------------------------------------------------------------+
<table>
<thead>
<tr>
<th>@@version</th>
<th>group_replication_get_communication_protocol()</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.4.0</td>
<td>8.0.27</td>
</tr>
</tbody>
</table>
+------------------------------------------------------------+
```

As demonstrated, the MySQL 8.4 LTS series uses the 8.0.27 communication protocol.

For more information, see Section 20.5.1.4, “Setting a Group's Communication Protocol Version”.

### 20.8.2 Group Replication Offline Upgrade

To perform an offline upgrade of a Group Replication group, you remove each member from the group, perform an upgrade of the member and then restart the group as usual. In a multi-primary group you can shutdown the members in any order. In a single-primary group, shutdown each secondary first and then finally the primary. See Section 20.8.3.2, “Upgrading a Group Replication Member” for how to remove members from a group and shutdown MySQL.

Once the group is offline, upgrade all of the members. See Chapter 3, *Upgrading MySQL* for how to perform an upgrade. When all members have been upgraded, restart the members.

If you upgrade all the members of a replication group when they are offline and then restart the group, the members join using the new release's Group Replication communication protocol version, so that becomes the group's communication protocol version. If you have a requirement to allow members at earlier releases to join, you can use the `group_replication_set_communication_protocol()` function to downgrade the communication protocol version, specifying the MySQL Server version of the prospective group member that has the oldest installed server version.

### 20.8.3 Group Replication Online Upgrade

When you have a group running which you want to upgrade but you need to keep the group online to serve your application, you need to consider your approach to the upgrade. This section describes the different elements involved in an online upgrade, and various methods of how to upgrade your group.

#### 20.8.3.1 Online Upgrade Considerations

When upgrading an online group you should consider the following points:

- Regardless of the way which you upgrade your group, it is important to disable any writes to group members until they are ready to rejoin the group.

- When a member is stopped, the `super_read_only` variable is set to on automatically, but this change is not persisted.

#### 20.8.3.2 Upgrading a Group Replication Member

This section explains the steps required for upgrading a member of a group. This procedure is part of the methods described at Section 20.8.3.3, “Group Replication Online Upgrade Methods”. The process of upgrading a member of a group is common to all methods and is explained first. The way which you join upgraded members can depend on which method you are following, and other factors such as whether the group is operating in single-primary or multi-primary mode. How you upgrade the server
instance, using either the in-place or provision approach, does not impact on the methods described here.

The process of upgrading a member consists of removing it from the group, following your chosen method of upgrading the member, and then rejoicing the upgraded member to a group. The recommended order of upgrading members in a single-primary group is to upgrade all secondaries, and then upgrade the primary last. If the primary is upgraded before a secondary, a new primary using the older MySQL version is chosen, but there is no need for this step.

To upgrade a member of a group:

- Connect a client to the group member and issue `STOP GROUP_REPLICATION`. Before proceeding, ensure that the member's status is `OFFLINE` by monitoring the `replication_group_members` table.

- Disable Group Replication from starting up automatically so that you can safely connect to the member after upgrading and configure it without it rejoining the group by setting `group_replication_start_on_boot=0`.

  **Important**
  
  If an upgraded member has `group_replication_start_on_boot=1` then it could rejoin the group before you can perform the MySQL upgrade procedure and could result in issues. For example, if the upgrade fails and the server restarts again, then a possibly broken server could try to join the group.

- Stop the member, for example using `mysqladmin shutdown` or the `SHUTDOWN` statement. Any other members in the group continue running.

- Upgrade the member, using the in-place or provisioning approach. See Chapter 3, *Upgrading MySQL* for details. When restarting the upgraded member, because `group_replication_start_on_boot` is set to 0, Group Replication does not start on the instance, and therefore it does not rejoin the group.

- Once the MySQL upgrade procedure has been performed on the member, `group_replication_start_on_boot` must be set to 1 to ensure Group Replication starts correctly after restart. Restart the member.

- Connect to the upgraded member and issue `START GROUP_REPLICATION`. This rejoins the member to the group. The Group Replication metadata is in place on the upgraded server, therefore there is usually no need to reconfigure Group Replication. The server has to catch up with any transactions processed by the group while the server was offline. Once it has caught up with the group, it becomes an online member of the group.

  **Note**
  
  The longer it takes to upgrade a server, the more time that member is offline and therefore the more time it takes for the server to catch up when added back to the group.

When an upgraded member joins a group which has any member running an earlier MySQL Server version, the upgraded member joins with `super_read_only=on`. This ensures that no writes are made to upgraded members until all members are running the newer version. In a multi-primary mode group, when the upgrade has been completed successfully and the group is ready to process transactions, members that are intended as writeable primaries must be set to read-write mode. When all members of a group have been upgraded to the same release, they all change back to read-write mode automatically.

### 20.8.3.3 Group Replication Online Upgrade Methods

Choose one of the following methods of upgrading a Group Replication group:
Rolling In-Group Upgrade

This method is supported provided that servers running a newer version are not generating workload to the group while there are still servers with an older version in it. In other words servers with a newer version can join the group only as secondaries. In this method there is only ever one group, and each server instance is removed from the group, upgraded and then rejoined to the group.

This method is well suited to single-primary groups. When the group is operating in single-primary mode, if you require the primary to remain the same throughout (except when it is being upgraded itself), it should be the last member to be upgraded. The primary cannot remain as the primary unless it is running the lowest MySQL Server version in the group. After the primary has been upgraded, you can use the `group_replication_set_as_primary()` function to reappoint it as the primary. If you do not mind which member is the primary, the members can be upgraded in any order. The group elects a new primary whenever necessary from among the members running the lowest MySQL Server version, following the election policies described in Section 20.1.3.1, “Single-Primary Mode”.

For groups operating in multi-primary mode, during a rolling in-group upgrade the number of primaries is decreased, causing a reduction in write availability. This is because if a member joins a group when it is running a higher MySQL Server version than the lowest version that the existing group members are running, it automatically remains in read-only mode (`super_read_only=ON`).

For full information on version compatibility in a group and how this influences the behavior of a group during an upgrade process, see Section 20.8.1, “Combining Different Member Versions in a Group”.

Rolling Migration Upgrade

In this method you remove members from the group, upgrade them and then create a second group using the upgraded members. For groups operating in multi-primary mode, during this process the number of primaries is decreased, causing a reduction in write availability. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are upgrading the members, you need the group running the newer version to catch up with any transactions executed while the members were being upgraded. Therefore one of the servers in the new group is configured as a replica of a primary from the older group. This ensures that the new group catches up with the older group. Because this method relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of asynchronous source-replica replication, see Chapter 19, Replication. For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- remove members from the original group running the older server version one by one, see Section 20.8.3.2, “Upgrading a Group Replication Member”
- upgrade the server version running on the member, see Chapter 3, Upgrading MySQL. You can either follow an in-place or provision approach to upgrading.
- create a new group with the upgraded members, see Chapter 20, Group Replication. In this case you need to configure a new group name on each member (because the old group is still running and using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.
- set up an asynchronous replication channel between the old group and the new group, see Section 19.1.3.4, “Setting Up Replication Using GTIDs”. Configure the older primary to function as the asynchronous replication source server and the new group member as a GTID-based replica.

Before you can redirect your application to the new group, you must ensure that the new group has a suitable number of members, for example so that the group can handle the failure of a member. Issue
**Group Replication Online Upgrade**

SELECT * FROM performance_schema.replication_group_members and compare the initial group size and the new group size. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection and upgrade any missing members.

**Rolling Duplication Upgrade**

In this method you create a second group consisting of members which are running the newer version, and the data missing from the older group is replicated to the newer group. This assumes that you have enough servers to run both groups simultaneously. Due to the fact that during this process the number of primaries is not decreased, for groups operating in multi-primary mode there is no reduction in write availability. This makes rolling duplication upgrade well suited to groups operating in multi-primary mode. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are provisioning the members in the new group, you need the group running the newer version to catch up with any transactions executed while the members were being provisioned. Therefore one of the servers in the new group is configured as a replica of a primary from the older group. This ensures that the new group catches up with the older group. Because this method relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of asynchronous source-replica replication, see Chapter 19, *Replication*. For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- deploy a suitable number of members so that the group running the newer version can handle failure of a member
- take a backup of the existing data from a member of the group
- use the backup from the older member to provision the members of the new group, see Section 20.8.3.4, “Group Replication Upgrade with `mysqlbackup`” for one method.

**Note**
You must restore the backup to the same version of MySQL which the backup was taken from, and then perform an in-place upgrade. For instructions, see Chapter 3, *Upgrading MySQL*.

- create a new group with the upgraded members, see Chapter 20, *Group Replication*. In this case you need to configure a new group name on each member (because the old group is still running and using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.
- set up an asynchronous replication channel between the old group and the new group, see Section 19.1.3.4, “Setting Up Replication Using GTIDs”. Configure the older primary to function as the asynchronous replication source server and the new group member as a GTID-based replica.

Once the ongoing data missing from the newer group is small enough to be quickly transferred, you must redirect write operations to the new group. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection.

**20.8.3.4 Group Replication Upgrade with `mysqlbackup`**

As part of a provisioning approach you can use MySQL Enterprise Backup to copy and restore the data from a group member to new members. However you cannot use this technique to directly restore a backup taken from a member running an older version of MySQL to a member running a newer version of MySQL. The solution is to restore the backup to a new server instance which is running the same version of MySQL as the member which the backup was taken from, and then upgrade the instance. This process consists of:
Group Replication Variables

- Take a backup from a member of the older group using `mysqlbackup`. See Section 20.5.6, “Using MySQL Enterprise Backup with Group Replication”.
- Deploy a new server instance, which must be running the same version of MySQL as the older member where the backup was taken.
- Restore the backup from the older member to the new instance using `mysqlbackup`.
- Upgrade MySQL on the new instance, see Chapter 3, Upgrading MySQL.

Repeat this process to create a suitable number of new instances, for example to be able to handle a failover. Then join the instances to a group based on the Section 20.8.3.3, “Group Replication Online Upgrade Methods”.

20.9 Group Replication Variables

The next two sections contain information about MySQL server system and server status variables which are specific to the Group Replication plugin.

20.9.1 Group Replication System Variables

This section lists the system variables that are specific to the Group Replication plugin.

The name of each Group Replication system variable is prefixed with `group_replication_`.

Note

InnoDB Cluster uses Group Replication, but the default values of the Group Replication system variables may differ from the defaults documented in this section. For example, in InnoDB Cluster, the default value of `group_replication_communication_stack` is `MYSQL`, not `XCOM` as it is for a default Group Replication implementation.

For more information, see MySQL InnoDB Cluster.

Some system variables on a Group Replication group member, including some Group Replication-specific system variables and some general system variables, are group-wide configuration settings. These system variables must have the same value on all group members, and require a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to reboot a group where every member has been stopped, see Section 20.5.2, “Restarting a Group”.

If a running group has a value set for a group-wide configuration setting, and a joining member has a different value set for that system variable, the joining member cannot join the group until the value is changed to match. If the group has a value set for one of these system variables, and the joining member does not support the system variable, it cannot join the group.

The following system variables are group-wide configuration settings:

- `group_replication_single_primary_mode`
- `group_replication_enforce_update_everywhere_checks`
- `group_replication_gtid_assignment_block_size`
- `group_replication_view_change_uuid` (deprecated)
- `group_replication_paxos_single_leader`
- `group_replication_communication_stack` (a special case not policed by Group Replication’s own checks; see the system variable description for details)
Group Replication System Variables

- **default_table_encryption**
- **lower_case_table_names**

Group-wide configuration settings cannot be changed by the usual methods while Group Replication is running, but it is possible to use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to change the values of `group_replication_single_primary_mode` and `group_replication_enforce_update_everywhere_checks` while the group is still running. For more information, see Section 20.5.1.2, “Changing the Group Mode”.

Most system variables for Group Replication can have different values on different group members. For the following system variables, it is advisable to set the same value on all members of a group in order to avoid unnecessary rollback of transactions, failure of message delivery, or failure of message recovery:

- **group_replication_auto_increment_increment**
- **group_replication_communication_max_message_size**
- **group_replication_compression_threshold**
- **group_replication_message_cache_size**
- **group_replication_transaction_size_limit**

The value of `group_replication_preemptive_garbage_collection` must be the same on all group members.

Most system variables for Group Replication are described as dynamic, and their values can be changed while the server is running. However, in most cases, the change only takes effect after you stop and restart Group Replication on the group member using a `STOP GROUP_REPLICATION` statement followed by a `START GROUP_REPLICATION` statement. Changes to the following system variables take effect without stopping and restarting Group Replication:

- **group_replication_advertise_recovery_endpoints**
- **group_replication_autorejoin_tries**
- **group_replication_consistency**
- **group_replication_exit_state_action**
- **group_replication_flow_control_applier_threshold**
- **group_replication_flow_control_certifier_threshold**
- **group_replication_flow_control_hold_percent**
- **group_replication_flow_control_max_quota**
- **group_replication_flow_control_member_quota_percent**
- **group_replication_flow_control_min_quota**
- **group_replication_flow_control_min_recovery_quota**
- **group_replication_flow_control_mode**
- **group_replication_flow_control_period**
- **group_replication_flow_control_release_percent**
- **group_replication_force_members**
- **group_replication_ip_allowlist**
Group Replication System Variables

- `group_replication_member_expel_timeout`
- `group_replication_member_weight`
- `group_replication_transaction_size_limit`
- `group_replication_unreachable_majority_timeout`

When you change the values of any Group Replication system variables, bear in mind that if there is a point where Group Replication is stopped on every member at once by a `STOP GROUP_REPLICATION` statement or system shutdown, the group must be restarted by bootstrapping as if it was being started for the first time. For instructions on doing this safely, see Section 20.5.2, “Restarting a Group”. In the case of group-wide configuration settings, this is required, but if you are changing other settings, try to ensure that at least one member is running at all times.

**Important**

- A number of system variables for Group Replication are not completely validated during server startup if they are passed as command line arguments to the server. These system variables include `group_replication_group_name`, `group_replication_single_primary_mode`, `group_replication_force_members`, the SSL variables, and the flow control system variables. They are fully validated only after the server has started.

- System variables for Group Replication that specify IP addresses or host names for group members are not validated until a `START GROUP_REPLICATION` statement is issued. Group Replication's Group Communication System (GCS) is not available to validate the values until that point.

Server system variables specific to the Group Replication plugin, along with descriptions of their function or purpose, are listed here:

- `group_replication_advertise_recovery_endpoints`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-advertise-recovery-endpoints=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_advertise_recovery_endpoints</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>DEFAULT</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running. The change takes effect immediately on the member. However, a joining member that already received the previous value of the system variable continues to use that value. Only members that join after the value change receive the new value.

`group_replication_advertise_recovery_endpoints` specifies how a joining member can establish a connection to an existing member for state transfer for distributed recovery. The connection is used for both remote cloning operations and state transfer from the donor’s binary log.

A value of `DEFAULT`, which is the default setting, means joining members use the existing member’s standard SQL client connection, as specified by MySQL Server’s `hostname` and `port` system variables. If an alternative port number is specified by the `report_port` system variable, that
one is used instead. The Performance Schema table `replication_group_members` shows this connection's address and port number in the `MEMBER_HOST` and `MEMBER_PORT` fields.

Instead of `DEFAULT`, you can specify one or more distributed recovery endpoints, which the existing member advertises to joining members for them to use. Offering distributed recovery endpoints lets administrators control distributed recovery traffic separately from regular MySQL client connections to the group members. Joining members try each of the endpoints in turn in the order they are specified on the list.

Specify the distributed recovery endpoints as a comma-separated list of IP addresses and port numbers, for example:

```sql
GROUP_REPLICATION_ADVERTISE_RECOVERY_ENDPOINTS= "127.0.0.1:3306,127.0.0.1:4567,[::1]:3306=localhost:3306"
```

IPv4 and IPv6 addresses and host names can be used in any combination. IPv6 addresses must be specified in square brackets. Host names must resolve to a local IP address. Wildcard address formats cannot be used, and you cannot specify an empty list. Note that the standard SQL client connection is not automatically included on a list of distributed recovery endpoints. If you want to use it as an endpoint, you must include it explicitly on the list.

For details of how to select IP addresses and ports as distributed recovery endpoints, and how joining members use them, see Selecting addresses for distributed recovery endpoints. A summary of the requirements is as follows:

- The IP addresses do not have to be configured for MySQL Server, but they do have to be assigned to the server.
- The ports do have to be configured for MySQL Server using the `port`, `report_port`, or `admin_port` system variable.
- Appropriate permissions are required for the replication user for distributed recovery if the `admin_port` is used.
- The IP addresses do not need to be added to the Group Replication allowlist specified by the `group_replication_ip_allowlist` system variable.
- The SSL requirements for the connection are as specified by the `group_replication_recovery_ssl_*` options.

### group_replication_allow_local_lower_version_join

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-allow-local-lower-version-join[=\{OFF|ON\}]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>group_replication_allow_local_lower_version_join</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_allow_local_lower_version_join` allows the current server to join the group even if it is running a lower MySQL Server version than the group. With the default setting `OFF`, servers are not permitted to join a replication group if they are running a lower version than...
the existing group members. This standard policy ensures that all members of a group are able to exchange messages and apply transactions. Note that members running MySQL 8.0.17 or higher take into account the patch version of the release when checking their compatibility. Members running MySQL 8.0.16 or earlier take into account the major version only.

Set `group_replication_allow_local_lower_version_join` to `ON` only in the following scenarios:

- A server must be added to the group in an emergency in order to improve the group’s fault tolerance, and only older versions are available.
- You want to roll back an upgrade for one or more replication group members without shutting down the whole group and bootstrapping it again.

### Warning

Setting this option to `ON` does not make the new member compatible with the group, and allows it to join the group without any safeguards against incompatible behaviors by the existing members. To ensure the new member's correct operation, take both of the following precautions:

1. Before the server running the lower version joins the group, stop all writes on that server.
2. From the point where the server running the lower version joins the group, stop all writes on the other servers in the group.

Without these precautions, the server running the lower version is likely to experience difficulties and terminate with an error.

- `group_replication_auto_increment_increment`

| Command-Line Format | --group-replication-auto-increment-increment=#
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_auto_increment_increment</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>7</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

This system variable should have the same value on all group members. You cannot change the value of this system variable while Group Replication is running. You must stop Group Replication, change the value of the system variable, then restart Group Replication, on each of the group members. During this process, the value of the system variable is permitted to differ between group members, but some transactions on group members might be rolled back.

`group_replication_auto_increment_increment` determines the interval between successive values for auto-incremented columns for transactions that execute on this server instance. Adding an interval avoids the selection of duplicate auto-increment values for writes on group members, which causes rollback of transactions. The default value of 7 represents a balance between the number of usable values and the permitted maximum size of a replication group (9
Group Replication System Variables

members). If your group has more or fewer members, you can set this system variable to match the expected number of group members before Group Replication is started.

Important

Setting `group_replication_auto_increment_increment` has no effect when `group_replication_single_primary_mode` is ON.

When Group Replication is started on a server instance, the value of the server system variable `auto_increment_increment` is changed to this value, and the value of the server system variable `auto_increment_offset` is changed to the server ID. The changes are reverted when Group Replication is stopped. These changes are only made and reverted if `auto_increment_increment` and `auto_increment_offset` each have their default value of 1.

If their values have already been modified from the default, Group Replication does not alter them. The system variables are also not modified when Group Replication is in single-primary mode, where only one server writes.

• `group_replication_autorejoin_tries`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-autorejoin-tries=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_autorejoin_tries</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2016</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The system variable's current value is read when an issue occurs that means the behavior is needed.

`group_replication_autorejoin_tries` specifies the number of tries that a member makes to automatically rejoin the group if it is expelled, or if it is unable to contact a majority of the group before the `group_replication_unreachable_majority_timeout` setting is reached. When the member's expulsion or unreachable majority timeout is reached, it makes an attempt to rejoin (using the current plugin option values), then continues to make further auto-rejoin attempts up to the specified number of tries. After an unsuccessful auto-rejoin attempt, the member waits 5 minutes before the next try. If the specified number of tries is exhausted without the member rejoining or being stopped, the member proceeds to the action specified by the `group_replication_exit_state_action` system variable.

During and between auto-rejoin attempts, a member remains in super read only mode and does not accept writes, but reads can still be made on the member, with an increasing likelihood of stale reads over time. If you cannot tolerate the possibility of stale reads for any period of time, set `group_replication_autorejoin_tries` to 0. For more information on the auto-rejoin feature, and considerations when choosing a value for this option, see Section 20.7.7.3, “Auto-Rejoin”.

• `group_replication_bootstrap_group`

| Command-Line Format                  | `--group-replication-bootstrap-group=[OFF|ON]` |
|--------------------------------------|---------------------------------------------|
| System Variable                     | `group_replication_bootstrap_group`         |
Group Replication System Variables

**group_replication_bootstrap_group** configures this server to bootstrap the group. This system variable must only be set on one server, and only when starting the group for the first time or restarting the entire group. After the group has been bootstrapped, set this option to OFF. It should be set to OFF both dynamically and in the configuration files. Starting two servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

For instructions to bootstrap a group for the first time, see Section 20.2.1.5, “Bootstrapping the Group”. For instructions to safely bootstrap a group where transactions have been executed and certified, see Section 20.5.2, “Restarting a Group”.

- **group_replication_clone_threshold**

  **Command-Line Format**
  --group-replication-clone-threshold=#

  **System Variable**
  group_replication_clone_threshold

  **Scope**
  Global

  **Dynamic**
  Yes

  **SET_VAR Hint Applies**
  No

  **Type**
  Integer

  **Default Value**
  9223372036854775807

  **Minimum Value**
  1

  **Maximum Value**
  9223372036854775807

  **Unit**
  transactions

  The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

  **group_replication_clone_threshold** specifies the transaction gap, as a number of transactions, between the existing member (donor) and the joining member (recipient) that triggers the use of a remote cloning operation for state transfer to the joining member during the distributed recovery process. If the transaction gap between the joining member and a suitable donor exceeds the threshold, Group Replication begins distributed recovery with a remote cloning operation. If the transaction gap is below the threshold, or if the remote cloning operation is not technically possible, Group Replication proceeds directly to state transfer from a donor's binary log.

  **Warning**
  Do not use a low setting for **group_replication_clone_threshold** in an active group. If a number of transactions above the threshold takes place in the group while the remote cloning operation is in progress, the joining member triggers a remote cloning operation again after restarting, and could continue this indefinitely. To avoid this situation, ensure that you set the threshold to a number higher than the number of transactions that you would
Group Replication System Variables

Expect to occur in the group during the time taken for the remote cloning operation.

To use this function, both the donor and the joining member must be set up beforehand to support cloning. For instructions, see Section 20.5.4.2, “Cloning for Distributed Recovery”. When a remote cloning operation is carried out, Group Replication manages it for you, including the required server restart, provided that `group_replication_start_on_boot=ON` is set. If not, you must restart the server manually. The remote cloning operation replaces the existing data dictionary on the joining member, but Group Replication checks and does not proceed if the joining member has additional transactions that are not present on the other group members, because these transactions would be erased by the cloning operation.

The default setting (which is the maximum permitted sequence number for a transaction in a GTID) means that state transfer from a donor's binary log is virtually always attempted rather than cloning. However, note that Group Replication always attempts to execute a cloning operation, regardless of your threshold, if state transfer from a donor's binary log is impossible, for example because the transactions needed by the joining member are not available in the binary logs on any existing group member. If you do not want to use cloning at all in your replication group, do not install the clone plugin on the members.

- `group_replication_communication_debug_options`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-communication-debug-options=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_communication_debug_options</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>GCS_DEBUG_NONE</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>GCS_DEBUG_NONE</code></td>
</tr>
<tr>
<td></td>
<td><code>GCS_DEBUG_BASIC</code></td>
</tr>
<tr>
<td></td>
<td><code>GCS_DEBUG_TRACE</code></td>
</tr>
<tr>
<td></td>
<td><code>XCOM_DEBUG_BASIC</code></td>
</tr>
<tr>
<td></td>
<td><code>XCOM_DEBUG_TRACE</code></td>
</tr>
<tr>
<td></td>
<td><code>GCS_DEBUG_ALL</code></td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_communication_debug_options` configures the level of debugging messages to provide for the different Group Replication components, such as the Group Communication System (GCS) and the group communication engine (XCom, a Paxos variant). The debug information is stored in the `GCS_DEBUG_TRACE` file in the data directory.

The set of available options, specified as strings, can be combined. The following options are available:

- `GCS_DEBUG_NONE` disables all debugging levels for both GCS and XCom.
- `GCS_DEBUG_BASIC` enables basic debugging information in GCS.
Group Replication System Variables

- **GCS_DEBUG_TRACE** enables trace information in GCS.
- **XCOM_DEBUG_BASIC** enables basic debugging information in XCom.
- **XCOM_DEBUG_TRACE** enables trace information in XCom.
- **GCS_DEBUG_ALL** enables all debugging levels for both GCS and XCom.

Setting the debug level to **GCS_DEBUG_NONE** only has an effect when provided without any other option. Setting the debug level to **GCS_DEBUG_ALL** overrides all other options.

- **group_replication_communication_max_message_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-communication-max-message-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_communication_max_message_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10485760</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

This system variable should have the same value on all group members. You cannot change the value of this system variable while Group Replication is running. You must stop Group Replication, change the value of the system variable, then restart Group Replication, on each of the group members. During this process, the value of the system variable is permitted to differ between group members, but some transactions on group members might be rolled back.

**group_replication_communication_max_message_size** specifies a maximum message size for Group Replication communications. Messages greater than this size are automatically split into fragments that are sent separately and reassembled by the recipients. For more information, see Section 20.7.5, “Message Fragmentation”.

A maximum message size of 10485760 bytes (10 MiB) is set by default, which means that fragmentation is used by default. The greatest permitted value is the same as the maximum value of the **replica_max_allowed_packet** system variable, which is 1073741824 bytes (1 GB). The setting for **group_replication_communication_max_message_size** must be less than the **replica_max_allowed_packet** setting, because the applier thread cannot handle message fragments larger than the maximum permitted packet size. To switch off fragmentation, specify a zero value for **group_replication_communication_max_message_size**.

In order for members of a replication group to use fragmentation, the group's communication protocol version must be MySQL 8.0.16 or later. Use the **group_replication_get_communication_protocol()** function to view the group's communication protocol version. If a lower version is in use, group members do not fragment messages. You can use the **group_replication_set_communication_protocol()** function to set the group's communication protocol to a higher version if all group members support it. For more information, see Section 20.5.1.4, “Setting a Group's Communication Protocol Version”.

- **group_replication_communication_stack**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>group_replication_communication_stack</th>
</tr>
</thead>
</table>
Group Replication System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>XCOM</td>
</tr>
<tr>
<td>Valid Values</td>
<td>XCOM, MYSQL</td>
</tr>
</tbody>
</table>

Note

This system variable is effectively a group-wide configuration setting; although it can be set at runtime, a full reboot of the replication group is required for any change to take effect.

group_replication_communication_stack specifies whether the XCom communication stack or the MySQL communication stack is to be used to establish group communication connections between members. The XCom communication stack is Group Replication's own implementation, and does not support authentication or network namespaces. The MySQL communication stack is MySQL Server's native implementation, with support for authentication and network namespaces, and access to new security functions immediately on release. All members of a group must use the same communication stack.

When you use the MySQL communication stack in place of XCom, MySQL Server establishes each connection between group members using its own authentication and encryption protocols.

Note

If you are using InnoDB Cluster, the default value of group_replication_communication_stack is MYSQL.

For more information, see MySQL InnoDB Cluster.

Additional configuration is required when you set up a group to use MySQL's communication stack; see Section 20.6.1, "Communication Stack for Connection Security Management".

group_replication_communication_stack is effectively a group-wide configuration setting, and the setting must be the same on all group members. However, this is not policed by Group Replication's own checks for group-wide configuration settings. A member with a different value from the rest of the group cannot communicate with the other members at all, because the communication protocols are incompatible, so it cannot exchange information about its configuration settings.

This means that although the value of the system variable can be changed while Group Replication is running, and takes effect after you restart Group Replication on the group member, the member still cannot rejoin the group until the setting has been changed on all the members. You must therefore stop Group Replication on all of the members and change the value of the system variable on them all before you can restart the group. Because all of the members are stopped, a full reboot of the group (a bootstrap by a server with group_replication_bootstrap_group=ON) is required in order for the value change to take effect. For instructions to migrate from one communication stack to another, see Section 20.6.1, "Communication Stack for Connection Security Management".

- group_replication_components_stop_timeout

Command-Line Format

```
--group-replication-components-stop-timeout=#
```

System Variable

group_replication_components_stop_timeout
Group Replication System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_components_stop_timeout` specifies the time, in seconds, for which Group Replication waits for each of its modules to complete ongoing processes while shutting down. The component timeout applies after a `STOP GROUP_REPLICATION` statement is issued, which happens automatically during server restart or auto-rejoin.

The timeout is used to resolve situations in which Group Replication components cannot be stopped normally, which might happen if a member is expelled from the group while it is in an error state, or while a process such as MySQL Enterprise Backup is holding a global lock on tables on the member. In such situations, the member cannot stop the applier thread or complete the distributed recovery process to rejoin. `STOP GROUP_REPLICATION` does not complete until either the situation is resolved (for example, by the lock being released), or the component timeout expires and the modules are shut down regardless of their status.

The default value is 300 seconds, so that Group Replication components are stopped after 5 minutes if the situation is not resolved before that time, allowing the member to be restarted and to rejoin.

- `group_replication_compression_threshold`

  Command-Line Format
  
  `--group-replication-compression-threshold=#`

  System Variable
  
  `group_replication_compression_threshold`

  Scope
  
  Global

  Dynamic
  
  Yes

  SET_VAR Hint Applies
  
  No

  Type
  
  Integer

  Default Value
  
  1000000

  Minimum Value
  
  0

  Maximum Value
  
  4294967295

  Unit
  
  bytes

The threshold value in bytes above which compression is applied to messages sent between group members. If this system variable is set to zero, compression is disabled. The value of `group_replication_compression_threshold` should be the same on all group members.

Group Replication uses the LZ4 compression algorithm to compress messages sent in the group. Note that the maximum supported input size for the LZ4 compression algorithm is 2113929216 bytes. This limit is lower than the maximum possible value for the `group_replication_compression_threshold` system variable, which is matched to the maximum message size accepted by XCom. With the LZ4 compression algorithm, do not set a value
greater than 2113929216 bytes for `group replication compression threshold`, because transactions above this size cannot be committed when message compression is enabled.

For more information, see Section 20.7.4, “Message Compression”.

- `group replication consistency`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-consistency=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group replication consistency</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>BEFORE_ON_PRIMARY_FAILOVER</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>EVENTUAL</code></td>
</tr>
<tr>
<td></td>
<td><code>BEFORE_ON_PRIMARY_FAILOVER</code></td>
</tr>
<tr>
<td></td>
<td><code>BEFORE</code></td>
</tr>
<tr>
<td></td>
<td><code>AFTER</code></td>
</tr>
<tr>
<td></td>
<td><code>BEFORE_AND_AFTER</code></td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running. `group replication consistency` is a server system variable rather than a Group Replication plugin-specific variable, so a restart of Group Replication is not required for the change to take effect. Changing the session value of the system variable takes effect immediately, and changing the global value takes effect for new sessions that start after the change. The `GROUP_REPLICATION_ADMIN` privilege is required to change the global setting for this system variable.

`group replication consistency` controls the transaction consistency guarantee which a group provides. You can configure the consistency globally or per transaction. `group replication consistency` also configures the fencing mechanism used by newly elected primaries in single primary groups. The effect of the variable must be considered for both read only (RO) and read write (RW) transactions. The following list shows the possible values of this variable, in order of increasing transaction consistency guarantee:

- **EVENTUAL**

  Both RO and RW transactions do not wait for preceding transactions to be applied before executing. This was the behavior of Group Replication before this variable was added. A RW transaction does not wait for other members to apply a transaction. This means that a transaction could be externalized on one member before the others. This also means that in the event of a primary failover, the new primary can accept new RO and RW transactions before the previous primary transactions are all applied. RO transactions could result in outdated values, RW transactions could result in a rollback due to conflicts.

- **BEFORE_ON_PRIMARY_FAILOVER**

  New RO or RW transactions with a newly elected primary that is applying backlog from the old primary are held (not applied) until any backlog has been applied. This ensures that when a primary failover happens, intentionally or not, clients always see the latest value on the primary. This guarantees consistency, but means that clients must be able to handle the delay in the event that a backlog is being applied. Usually this delay should be minimal, but does depend on the size of the backlog.
The Group Replication System Variables document describes various consistency levels and a command-line variable for enforcing multi-primary update everywhere checks.

### BEFORE

A RW transaction waits for all preceding transactions to complete before being applied. A RO transaction waits for all preceding transactions to complete before being executed. This ensures that this transaction reads the latest value by only affecting the latency of the transaction. This reduces the overhead of synchronization on every RW transaction, by ensuring synchronization is used only on RO transactions. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

### AFTER

A RW transaction waits until its changes have been applied to all of the other members. This value has no effect on RO transactions. This mode ensures that when a transaction is committed on the local member, any subsequent transaction reads the written value or a more recent value on any group member. Use this mode with a group that is used for predominantly RO operations to ensure that applied RW transactions are applied everywhere once they commit. This could be used by your application to ensure that subsequent reads fetch the latest data which includes the latest writes. This reduces the overhead of synchronization on every RO transaction, by ensuring synchronization is used only on RW transactions. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

### BEFORE_AND_AFTER

A RW transaction waits for all preceding transactions to complete before being applied, and until its changes have been applied on other members. A RO transaction waits for all preceding transactions to complete before execution takes place. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

For more information, see Section 20.5.3, “Transaction Consistency Guarantees”.

### `group_replication_enforce_update_everywhere_checks`

- **Command-Line Format**
  
  `--group-replication-enforce-update-everywhere-checks[={OFF|ON}]`

- **System Variable**
  
  `group_replication_enforce_update_everywhere_checks`

- **Scope**
  
  Global

- **Dynamic**
  
  Yes

- **SET_VAR**
  
  No

- **Type**
  
  Boolean

- **Default Value**
  
  OFF

**Note**

This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

`group_replication_enforce_update_everywhere_checks` enables or disables strict consistency checks for multi-primary update everywhere. The default is that checks are disabled. In single-primary mode, this option must be disabled on all group members. In multi-primary mode, when this option is enabled, statements are checked as follows to ensure they are compatible with multi-primary mode:

- If a transaction is executed under the `SERIALIZABLE` isolation level, then its commit fails when synchronizing itself with the group.

- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.
This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see Section 20.5.2, "Restarting a Group".

If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

Use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to change the value of this system variable while the group is still running. For more information, see Section 20.5.1.2, "Changing the Group Mode".

```
• group_replication_exit_state_action
```

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-exit-state-action=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_exit_state_action</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFFLINE_MODE</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>ABORT_SERVER</code></td>
</tr>
<tr>
<td></td>
<td><code>OFFLINE_MODE</code></td>
</tr>
<tr>
<td></td>
<td><code>READONLY</code></td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The system variable’s current value is read when an issue occurs that means the behavior is needed.

`group_replication_exit_state_action` configures how Group Replication behaves when this server instance leaves the group unintentionally, for example after encountering an applier error, or in the case of a loss of majority, or when another member of the group expels it due to a suspicion timing out. The timeout period for a member to leave the group in the case of a loss of majority is set by the `group_replication_unreachable_majority_timeout` system variable, and the timeout period for suspicions is set by the `group_replication_member_expel_timeout` system variable. Note that an expelled group member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

When a group member is expelled due to a suspicion timing out or a loss of majority, if the member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it first makes the specified number of attempts while in super read only mode,
and then follows the action specified by `group_replication_exit_state_action`. Auto-rejoin attempts are not made in case of an applier error, because these are not recoverable.

When `group_replication_exit_state_action` is set to `READ_ONLY`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance switches MySQL to super read only mode (by setting the system variable `super_read_only` to `ON`).

When `group_replication_exit_state_action` is set to `OFFLINE_MODE`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance switches MySQL to offline mode (by setting the system variable `offline_mode` to `ON`). In this mode, connected client users are disconnected on their next request and connections are no longer accepted, with the exception of client users that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). Group Replication also sets the system variable `super_read_only` to `ON`, so clients cannot make any updates, even if they have connected with the `CONNECTION_ADMIN` or `SUPER` privilege.

When `group_replication_exit_state_action` is set to `ABORT_SERVER`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance shuts down MySQL.

**Important**

If a failure occurs before the member has successfully joined the group, the specified exit action is not taken. This is the case if there is a failure during the local configuration check, or a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the `super_read_only` system variable is left with its original value, connections continue to be accepted, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that `super_read_only=ON` is set in the server's configuration file at startup, which Group Replication changes to `OFF` on primary members after it has been started successfully. This safeguard is particularly important when the server is configured to start Group Replication on server boot (`group_replication_start_on_boot=ON`), but it is also useful when Group Replication is started manually using a `START GROUP_REPLICATION` command.

For more information on using this option, and the full list of situations in which the exit action is taken, see Section 20.7.7.4, “Exit Action”.

<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

group_replication_flow_control_max_quota defines the maximum flow control quota of the group, or the maximum available quota for any period while flow control is enabled. A value of 0 implies that there is no maximum quota set. The value of this system variable cannot be smaller than group_replication_flow_control_min_quota and group_replication_flow_control_min_recovery_quota.

• **group_replication_flow_control_member_quota_percent**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-flow-control-member-quota-percent=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_flow_control_member_quota_percent</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>

</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

group_replication_flow_control_member_quota_percent defines the percentage of the quota that a member should assume is available for itself when calculating the quotas. A value of 0 implies that the quota should be split equally between members that were writers in the last period.

• **group_replication_flow_control_min_quota**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-flow-control-min-quota=#</th>

### Group Replication System Variables

<table>
<thead>
<tr>
<th>SET_VAR Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_min_quota` controls the lowest flow control quota that can be assigned to a member, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. The value of this system variable cannot be larger than `group_replication_flow_control_max_quota`.

- **group_replication_flow_control_min_recovery_quota**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-flow-control-min-recovery-quota=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_flow_control_min_recovery_quota</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_min_recovery_quota` controls the lowest quota that can be assigned to a member because of another recovering member in the group, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. The value of this system variable cannot be larger than `group_replication_flow_control_max_quota`.

  Yes

  `SET_VAR` Hint Applies
  No

  Type
  Integer

  Default Value
  1

  Minimum Value
  1

  Maximum Value
  60

  Unit
  seconds

  The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

  `group_replication_flow_control_period` defines how many seconds to wait between flow control iterations, in which flow control messages are sent and flow control management tasks are run.

  - **`group_replication_flow_control_release_percent`**

    Command-Line Format
    ```
    --group-replication-flow-control-release-percent=#
    ```

    System Variable
    `group_replication_flow_control_release_percent`

    Scope
    Global

    Dynamic
    Yes

    `SET_VAR` Hint Applies
    No

    Type
    Integer

    Default Value
    50

    Minimum Value
    0

    Maximum Value
    1000

    Unit
    percentage

    The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

    `group_replication_flow_control_release_percent` defines how the group quota should be released when flow control no longer needs to throttle the writer members, with this percentage being the quota increase per flow control period. A value of 0 implies that once the flow control thresholds are within limits the quota is released in a single flow control iteration. The range allows the quota to be released at up to 10 times current quota, as that allows a greater degree of adaptation, mainly when the flow control period is large and the quotas are very small.
**group_replication_force_members**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-force-members=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_force_members</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This system variable is used to force a new group membership. The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. You only need to set the value of the system variable on one of the group members that is to remain in the group. For details of the situation in which you might need to force a new group membership, and a procedure to follow when using this system variable, see Section 20.7.8, “Handling a Network Partition and Loss of Quorum”.

`group_replication_force_members` specifies a list of peer addresses as a comma separated list, such as `host1:port1,host2:port2`. Any existing members that are not included in the list do not receive a new view of the group and are blocked. For each existing member that is to continue as a member, you must include the IP address or host name and the port, as they are given in the `group_replication_local_address` system variable for each member. An IPv6 address must be specified in square brackets. For example:

```
"198.51.100.44:33061, [2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061, example.org:33061"
```

The group communication engine for Group Replication (XCom) checks that the supplied IP addresses are in a valid format, and checks that you have not included any group members that are currently unreachable. Otherwise, the new configuration is not validated, so you must be careful to include only online servers that are reachable members of the group. Any incorrect values or invalid host names in the list could cause the group to be blocked with an invalid configuration.

It is important before forcing a new membership configuration to ensure that the servers to be excluded have been shut down. If they are not, shut them down before proceeding. Group members that are still online can automatically form new configurations, and if this has already taken place, forcing a further new configuration could create an artificial split-brain situation for the group.

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

**group_replication_group_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-group-name=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_group_name</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The value of this system variable cannot be changed while Group Replication is running.

`group_replication_group_name` specifies the name of the group which this server instance belongs to, which must be a valid UUID. This UUID forms part of the GTIDs that are used when
transactions received by group members from clients, and view change events that are generated internally by the group members, are written to the binary log.

![Important]

A unique UUID must be used.

- **group replication group seeds**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-group-seeds=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_group_seeds</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

group_replication_group_seeds is a list of group members to which a joining member can connect to obtain details of all the current group members. The joining member uses these details to select and connect to a group member to obtain the data needed for synchrony with the group. The list consists of a single internal network address or host name for each included seed member, as configured in the seed member's group_replication_local_address system variable (not the seed member's SQL client connection, as specified by MySQL Server's hostname and port system variables). The addresses of the seed members are specified as a comma separated list, such as host1:port1,host2:port2. An IPv6 address must be specified in square brackets. For example:

group_replication_group_seeds= "198.51.100.44:33061,[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061, example.org:33061"

Note that the value you specify for this variable is not validated until a START GROUP_REPLICATION statement is issued and the Group Communication System (GCS) is available.

Usually this list consists of all members of the group, but you can choose a subset of the group members to be seeds. The list must contain at least one valid member address. Each address is validated when starting Group Replication. If the list does not contain any valid member addresses, issuing START GROUP_REPLICATION fails.

When a server is joining a replication group, it attempts to connect to the first seed member listed in its group_replication_group_seeds system variable. If the connection is refused, the joining member tries to connect to each of the other seed members in the list in order. If the joining member connects to a seed member but does not get added to the replication group as a result (for example, because the seed member does not have the joining member's address in its allowlist and closes the connection), the joining member continues to try the remaining seed members in the list in order.

A joining member must communicate with the seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the group_replication_group_seeds option. For the purpose of IP address permissions for Group Replication, the allowlist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and permitted in addition to the joining member's group_replication_local_address if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information, see Section 20.6.4, “Group Replication IP Address Permissions”.
**Group Replication System Variables**

- **group_replication_gtid_assignment_block_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-gtid-assignment-block-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_gtid_assignment_block_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>

</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>9223372036854775807</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

**Note**

This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

*group_replication_gtid_assignment_block_size* specifies the number of consecutive GTIDs that are reserved for each group member. Each member consumes its own blocks and reserves more when needed.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see Section 20.5.2, “Restarting a Group”.

If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

- **group_replication_ip_allowlist**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-ip-allowlist=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_ip_allowlist</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>AUTOMATIC</td>
</tr>
</tbody>
</table>

*group_replication_ip_allowlist* specifies which hosts are permitted to connect to the group. When the XCom communication stack is in use for the group (*group_replication_communication_stack=XCOM*), the allowlist is used to control access to the group. When the MySQL communication stack is in use for the group
Group Replication System Variables

(group_replication_communication_stack=MYSQL), user authentication is used to control access to the group, and the allowlist is not used and is ignored if set.

The address that you specify for each group member in group_replication_local_address must be permitted on the other servers in the replication group. Note that the value you specify for this variable is not validated until a START GROUP_REPLICATION statement is issued and the Group Communication System (GCS) is available.

By default, this system variable is set to AUTOMATIC, which permits connections from private subnetworks active on the host. The group communication engine for Group Replication (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks. These addresses and the localhost IP address for IPv4 and IPv6 are used to create the Group Replication allowlist. For a list of the ranges from which addresses are automatically permitted, see Section 20.6.4, “Group Replication IP Address Permissions”.

The automatic allowlist of private addresses cannot be used for connections from servers outside the private network. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit allowlist. If you specify any entries for the allowlist, the private addresses are not added automatically, so if you use any of these, you must specify them explicitly. The localhost IP addresses are added automatically.

As the value of the group_replication_ip_allowlist option, you can specify any combination of the following:

- IPv4 addresses (for example, 198.51.100.44)
- IPv4 addresses with CIDR notation (for example, 192.0.2.21/24)
- IPv6 addresses (for example, 2001:db8:85a3:8d3:1319:8a2e:370:7348)
- IPv6 addresses with CIDR notation (for example, 2001:db8:85a3:8d3::/64)
- Host names (for example, example.org)
- Host names with CIDR notation (for example, www.example.com/24)

Host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can use CIDR notation in combination with host names or IP addresses to permit a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

A comma must separate each entry in the allowlist. For example:

*192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,example.org,www.example.com/24*

If any of the seed members for the group are listed in the group_replication_group_seeds option with an IPv6 address when a joining member has an IPv4 group_replication_local_address, or the reverse, you must also set up and permit an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). For more information, see Section 20.6.4, “Group Replication IP Address Permissions”.

It is possible to configure different allowlists on different group members according to your security requirements, for example, in order to keep different subnets separate. However, this can cause issues when a group is reconfigured. If you do not have a specific security requirement to do
other, use the same allowlist on all members of a group. For more details, see Section 20.6.4, “Group Replication IP Address Permissions”.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for allowlist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

**Warning**

Host names are inherently less secure than IP addresses in an allowlist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

- `group_replication_local_address`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-local-address=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_local_address</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_local_address` sets the network address which the member provides for connections from other members, specified as a `host:port` formatted string. This address must be reachable by all members of the group because it is used by the group communication engine for Group Replication (XCom, a Paxos variant) for TCP communication between remote XCom instances. If you are using the MySQL communication stack to establish group communication connections between members (`group_replication_communication_stack = MYSQL`), the address must be one of the IP addresses and ports where MySQL Server is listening on, as specified by the `bind_address` system variable for the server.

**Warning**

Do not use this address to query or administer the databases on the member. This is not the SQL client connection host and port.

The address or host name that you specify in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, and you can use the same host name or IP address for all members as long as the ports are all different. The recommended port for `group_replication_local_address` is 33061. Note that the value you specify for this variable is not validated until the `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a
Group Replication System Variables

host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured /etc/hosts files, or other name resolution processes. An IPv6 address must be specified in square brackets in order to distinguish the port number, for example:

```
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. For more information on Group Replication support for IPv6 networks and on replication groups with a mix of members using IPv4 and members using IPv6, see Section 20.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.

If you are using the XCom communication stack to establish group communication connections between members (group_replication_communication_stack = XCOM), the address that you specify for each group member in group_replication_local_address must be added to the list for the group_replication_ip_allowlist system variable on the other servers in the replication group. When the XCom communication stack is in use for the group, the allowlist is used to control access to the group. When the MySQL communication stack is in use for the group, user authentication is used to control access to the group, and the allowlist is not used and is ignored if set. Note that if any of the seed members for the group are listed in the group_replication_group_seeds option with an IPv6 address when this member has an IPv4 group_replication_local_address, or the reverse, you must also set up and permit an alternative address for this member for the required protocol (or a host name that resolves to an address for that protocol). For more information, see Section 20.6.4, “Group Replication IP Address Permissions”.

• group_replication_member_expel_timeout

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-member-expel-timeout=</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_member_expel_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3600</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The current value of the system variable is read whenever Group Replication checks the timeout. It is not mandatory for all members of a group to have the same setting, but it is recommended in order to avoid unexpected expulsions.

group_replication_member_expel_timeout specifies the period of time in seconds that a Group Replication group member waits after creating a suspicion, before expelling from the group the member suspected of having failed. The initial 5-second detection period before a suspicion is created does not count as part of this time. The value of group_replication_member_expel_timeout defaults to 5, meaning that a suspected member is liable for expulsion 5 seconds after the 5-second detection period.

Changing the value of group_replication_member_expel_timeout on a group member takes effect immediately for existing as well as future suspicions on that group member. You can therefore use this as a method to force a suspicion to time out and expel a suspected member, allowing changes to the group configuration. For more information, see Section 20.7.7.1; “Expel Timeout”.
Increasing the value of `group_replication_member_expel_timeout` can help to avoid unnecessary expulsions on slower or less stable networks, or in the case of expected transient network outages or machine slowdowns. If a suspect member becomes active again before the suspicion times out, it applies all the messages that were buffered by the remaining group members and enters ONLINE state, without operator intervention. You can specify a timeout value up to a maximum of 3600 seconds (1 hour). It is important to ensure that XCom’s message cache is sufficiently large to contain the expected volume of messages in your specified time period, plus the initial 5-second detection period, otherwise members are unable to reconnect. You can adjust the cache size limit using the `group_replication_message_cache_size` system variable. For more information, see Section 20.7.6, “XCom Cache Management”.

If the timeout is exceeded, the suspect member is liable for expulsion immediately after the suspicion times out. If the member is able to resume communications and receives a view where it is expelled, and the member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it proceeds to make the specified number of attempts to rejoin the group while in super read only mode. If the member does not have any auto-rejoin attempts specified, or if it has exhausted the specified number of attempts, it follows the action specified by the system variable `group_replication_exit_state_action`.

For more information on using the `group_replication_member_expel_timeout` setting, see Section 20.7.7.1, “Expel Timeout”. For alternative mitigation strategies to avoid unnecessary expulsions where this system variable is not available, see Section 20.3.2, “Group Replication Limitations”.

- `group_replication_member_weight`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-member-weight=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_member_weight</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>No</td>
</tr>
<tr>
<td>Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
<tr>
<td>Unit</td>
<td>percentage</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The system variable’s current value is read when a failover situation occurs.

`group_replication_member_weight` specifies a percentage weight that can be assigned to members to influence the chance of the member being elected as primary in the event of failover, for example when the existing primary leaves a single-primary group. Assign numeric weights to members to ensure that specific members are elected, for example during scheduled maintenance of the primary or to ensure certain hardware is prioritized in the event of failover.

For a group with members configured as follows:

- `member-1`: `group_replication_member_weight=30, server_uuid=aaaa`
- `member-2`: `group_replication_member_weight=40, server_uuid=bbbb`
- `member-3`: `group_replication_member_weight=40, server_uuid=cccc`
• **member-4**: `group_replication_member_weight=40, server_uuid=dddd`

during election of a new primary the members above would be sorted as `member-2, member-3, member-4, and member-1`. This results in `member-2` being chosen as the new primary in the event of failover. For more information, see Section 20.1.3.1, “Single-Primary Mode”.

• **group_replication_message_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-message-cache-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_message_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824 (1 GB)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>134217728 (128 MB)</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615 (16 EiB)</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>315360004294967295 (4 GB)</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

This system variable should have the same value on all group members. The value of this system variable can be changed while Group Replication is running. The change takes effect on each group member after you stop and restart Group Replication on the member. During this process, the value of the system variable is permitted to differ between group members, but members might be unable to reconnect in the event of a disconnection.

`group_replication_message_cache_size` sets the maximum amount of memory that is available for the message cache in the group communication engine for Group Replication (XCom). The XCom message cache holds messages (and their metadata) that are exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery of missed messages by members that reconnect with the group after a period where they were unable to communicate with the other group members.

The `group_replication_member_expel_timeout` system variable determines the waiting period (up to an hour) that is allowed in addition to the initial 5-second detection period for members to return to the group rather than being expelled. The size of the XCom message cache should be set with reference to the expected volume of messages in this time period, so that it contains all the missed messages required for members to return successfully. The default is a 5-second waiting period after the 5-second detection period, for a total time period of 10 seconds.

Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of MySQL Server’s other caches and object pools. The default setting is 1073741824 bytes (1 GB). The minimum setting of 134217728 bytes (128 MB) enables deployment on a host that has a restricted amount of available memory, and good network connectivity to minimize the frequency and duration of transient losses of connectivity for group members. Note that the limit set using `group_replication_message_cache_size` applies only to the data stored in the cache, and the cache structures require an additional 50 MB of memory.

The cache size limit can be increased or reduced dynamically at runtime. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. Group Replication’s Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is
Group Replication System Variables

Currently unreachable is removed from the message cache. For more information on tuning the message cache size, see Section 20.7.6, “XCom Cache Management”.

- **group_replication_paxos_single_leader**

  **Command-Line Format**
  ```
  --group-replication-paxos-single-leader[={OFF|ON}]
  ```

  **System Variable**
  `group_replication_paxos_single_leader`

  **Scope**
  Global

  **Dynamic**
  Yes

  **SET_VAR Hint Applies**
  No

  **Type**
  Boolean

  **Default Value**
  OFF

  **Note**
  This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

  The system variable `group_replication_paxos_single_leader` enables the group communication engine to operate with a single consensus leader when the group is in single-primary mode. With the default setting OFF, this behavior is disabled, and every member of the group is used as a leader, which is the behavior in releases before this system variable was available. When the system variable is set to ON, the group communication engine can use a single leader to drive consensus. Operating with a single consensus leader improves performance and resilience in single-primary mode, particularly when some of the group’s secondary members are currently unreachable. For more information, see Section 20.7.3, “Single Consensus Leader”.

  In order for the group communication engine to use a single consensus leader, the group’s communication protocol version must be MySQL 8.0.27 or later. Use the `group_replication_get_communication_protocol()` function to view the group’s communication protocol version. If a lower version is in use, the group cannot use this behavior. You can use the `group_replication_set_communication_protocol()` function to set the group’s communication protocol to a higher version if all group members support it. For more information, see Section 20.5.1.4, “Setting a Group’s Communication Protocol Version”.

  This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see Section 20.5.2, “Restarting a Group”.

  If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

  The field `WRITE_CONSENSUS_SINGLE_LEADER.Capable` in the Performance Schema table `replication_group_communication_information` shows whether the group supports the use of a single leader, even if `group_replication_paxos_single_leader` is currently set to OFF on the queried member. The field is set to 1 if the group was started with `group_replication_paxos_single_leader` set to ON, and its communication protocol version is MySQL 8.0.27 or later.
Group Replication System Variables

- **group_replication_poll_spin_loops**

  Command-Line Format
  
  ```
  --group-replication-poll-spin-loops=#
  ```

  System Variable
  
  ```
  group_replication_poll_spin_loops
  ```

  Scope
  
  Global

  Dynamic
  
  Yes

  SET_VAR Hint Applies
  
  No

  Type
  
  Integer

  Default Value
  
  0

  Minimum Value
  
  0

  Maximum Value (64-bit platforms)
  
  18446744073709551615

  Maximum Value (32-bit platforms)
  
  4294967295

  The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

  `group_replication_poll_spin_loops` specifies the number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

- **group_replication_preemptive_garbage_collection**

  Command-Line Format
  
  ```
  --group-replication-preemptive-garbage-collection=[ON|OFF]
  ```

  System Variable
  
  ```
  group_replication_preemptive_garbage_collection
  ```

  Scope
  
  Global

  Dynamic
  
  Yes

  SET_VAR Hint Applies
  
  No

  Type
  
  Boolean

  Default Value
  
  OFF

  Enable preemptive garbage collection in single-primary mode (only), keeping only the write sets for those transactions that have not yet been committed in the database.

  The value of this system variable can be changed only when Group Replication is not running, and has no effect on a group running in multi-primary mode. To change from multi-primary mode and single-primary mode, use the `group_replication_switch_to_single_primary_mode()` function; see Section 20.5.1.2, "Changing the Group Mode", for more information.

  `group_replication_preemptive_garbage_collection` must be set to the same value on all group members. A new joiner's `group_replication_preemptive_garbage_collection` value must be the same as those of all the group's current members, else it cannot join.

  A group member running a version of MySQL previous to 8.4.0 sends no `group_replication_preemptive_garbage_collection` value; in such cases, the value is considered to be OFF.

- **group_replication_preemptive_garbage_collection_rows_threshold**

  Command-Line Format
  
  ```
  --group-replication-preemptive-garbage-collection-rows-threshold=#
  ```

  System Variable
  
  ```
  group_replication_preemptive_garbage_collection_rows_threshold
  ```

  3684
### Group Replication System Variables

<table>
<thead>
<tr>

</tr>
<tr>
<td>Minimum Value</td>
<td>10000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10000000</td>
</tr>
</tbody>
</table>

When preemptive garbage collection in single-primary mode is enabled (`group_replication_preemptive_garbage_collection` is ON), this is the number of rows of certification information needed to trigger its use.

This variable has no effect on a group running in multi-primary mode.

- `group_replication_recovery_compression_algorithms`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-recovery-compression-algorithms=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_recovery_compression_algorithms</code></td>
</tr>
<tr>

<td><code>uncompressed</code></td>
</tr>
</tbody>
</table>

`group_replication_recovery_compression_algorithms` specifies the compression algorithms permitted for Group Replication distributed recovery connections for state transfer from a donor’s binary log. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. For more information, see Section 6.2.8, “Connection Compression Control”.

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

This setting does not apply if the server has been set up to support cloning (see Section 20.5.4.2, “Cloning for Distributed Recovery”) and a remote cloning operation is used during distributed recovery. For this method of state transfer, the clone plugin’s `clone_enable_compression` setting applies.

- `group_replication_recovery_get_public_key`

  | Command-Line Format                     | `--group-replication-recovery-get-public-key=[OFF|ON]` |
|-----------------------------------------|-------------------------------------------------------|
| System Variable                        | `group_replication_recovery_get_public_key`            |
| Scope                                  | Global                                                |
| Dynamic                                | Yes                                                   |
| **SET_VAR** Hint Applies                | No                                                    |
Group Replication System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_get_public_key` specifies whether to request from the source the public key required for RSA key pair-based password exchange. If `group_replication_recovery_public_key_path` is set to a valid public key file, it takes precedence over `group_replication_recovery_get_public_key`. This variable applies if you are not using SSL for distributed recovery over the `group_replication_recovery` channel (`group_replication_recovery_use_ssl=ON`), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (the default). For more details, see Replication User With The Caching SHA-2 Authentication Plugin.

- **`group_replication_recovery_reconnect_interval`**

  **Command-Line Format**
  
  `--group-replication-recovery-reconnect-interval=#`

  **System Variable**
  
  `group_replication_recovery_reconnect_interval`

  **Scope**
  
  Global

  **Dynamic**
  
  Yes

  **SET_VAR Hint Applies**
  
  No

  **Type**
  
  Integer

  **Default Value**
  
  60

  **Minimum Value**
  
  0

  **Maximum Value**
  
  31536000
Group Replication System Variables

<table>
<thead>
<tr>
<th>Unit</th>
<th>seconds</th>
</tr>
</thead>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_reconnect_interval` specifies the sleep time, in seconds, between reconnection attempts when no suitable donor was found in the group for distributed recovery.

- `group_replication_recovery_retry_count`

Command-Line Format

```
--group-replication-recovery-retry-count=#
```

System Variable

`group_replication_recovery_retry_count`

Scope

Global

Dynamic

Yes

`SET_VAR` Hint Applies

No

Type

Integer

Default Value

10

Minimum Value

0

Maximum Value

31536000

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_retry_count` specifies the number of times that the member that is joining tries to connect to the available donors for distributed recovery before giving up.

- `group_replication_recovery_ssl_ca`

Command-Line Format

```
--group-replication-recovery-ssl-ca=value
```

System Variable

`group_replication_recovery_ssl_ca`

Scope

Global

Dynamic

Yes

`SET_VAR` Hint Applies

No

Type

String

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_ca` specifies the path to a file that contains a list of trusted SSL certificate authorities for distributed recovery connections. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see Section 20.5.4.2, “Cloning for Distributed Recovery”), and you have set `group_replication_recovery_use_ssl` to ON, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_ca` to match your setting for `group_replication_recovery_ssl_ca`.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.
### Group Replication System Variables

**• group_replication_recovery_ssl_capath**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-recovery-ssl-capath=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_recovery_ssl_capath</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_capath` specifies the path to a directory that contains trusted SSL certificate authority certificates for distributed recovery connections. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

**• group_replication_recovery_ssl_cert**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-recovery-ssl-cert=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_recovery_ssl_cert</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_cert` specifies the name of the SSL certificate file to use for establishing a secure connection for distributed recovery. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see Section 20.5.4.2, “Cloning for Distributed Recovery”), and you have set `group_replication_recovery_use_ssl` to ON, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_cert` to match your setting for `group_replication_recovery_ssl_cert`.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

**• group_replication_recovery_ssl_cipher**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-recovery-ssl-cipher=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_recovery_ssl_cipher</td>
</tr>
</tbody>
</table>

If this server has been set up to support cloning (see Section 20.5.4.2, “Cloning for Distributed Recovery”), and you have set `group_replication_recovery_use_ssl` to ON, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_cipher` to match your setting for `group_replication_recovery_ssl_cipher`.
Group Replication System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_cipher` specifies the list of permissible ciphers for SSL encryption. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_ssl_crl`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-recovery-ssl-crl=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_recovery_ssl_crl</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_crl` specifies the path to a directory that contains files containing certificate revocation lists. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_ssl_crlpath`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-recovery-ssl-crlpath=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_recovery_ssl_crlpath</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_crlpath` specifies the path to a directory that contains files containing certificate revocation lists. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.
Connections with Secure Socket Layer (SSL)* for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (group_replication_communication_stack = MYSQL), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- **group_replication_recovery_ssl_key**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-recovery-ssl-key=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_recovery_ssl_key</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

**group_replication_recovery_ssl_key** specifies the name of the SSL key file to use for establishing a secure connection. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see Section 20.5.4.2, “Cloning for Distributed Recovery”), and you have set `group_replication_recovery_use_ssl` to ON, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_key` to match your setting for `group_replication_recovery_ssl_key`.

When the MySQL communication stack is in use for the group (group_replication_communication_stack = MYSQL), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- **group_replication_recovery_ssl_verify_server_cert**

  | Command-Line Format | `--group-replication-recovery-ssl-verify-server-cert[={OFF|ON}]` |
  |---------------------|---------------------------------------------------------------|
  | System Variable     | `group_replication_recovery_ssl_verify_server_cert`          |
  | Scope               | Global                                                        |
  | Dynamic             | Yes                                                           |
  | SET_VAR Hint Applies| No                                                            |
  | Type                | Boolean                                                       |
  | Default Value       | OFF                                                           |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

**group_replication_recovery_ssl_verify_server_cert** specifies whether the distributed recovery connection should check the server’s Common Name value in the certificate sent by the donor. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (group_replication_communication_stack = MYSQL), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.
• \texttt{group\_replication\_recovery\_tls\_ciphersuites}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--\texttt{group-replication-recovery-tls-ciphersuites=\texttt{value}}</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>\texttt{group_replication_recovery_tls_ciphersuites}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR}</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

\texttt{group\_replication\_recovery\_tls\_ciphersuites} specifies a colon-separated list of one or more permitted ciphersuites when TLSv1.3 is used for connection encryption for the distributed recovery connection, and this server instance is the client in the distributed recovery connection, that is, the joining member. If this system variable is set to \texttt{NULL} when TLSv1.3 is used (which is the default if you do not set the system variable), the ciphersuites that are enabled by default are allowed, as listed in Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”. If this system variable is set to the empty string, no cipher suites are allowed, and TLSv1.3 is therefore not used. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)”, for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (\texttt{group\_replication\_communication\_stack = MYSQL}), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

• \texttt{group\_replication\_recovery\_tls\_version}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--\texttt{group-replication-recovery-tls-version=\texttt{value}}</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>\texttt{group_replication_recovery_tls_version}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR}</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>TLSv1.2,TLSv1.3</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

\texttt{group\_replication\_recovery\_tls\_version} specifies a comma-separated list of one or more permitted TLS protocols for connection encryption when this server instance is the client in the distributed recovery connection, that is, the joining member. The group members involved in
each distributed recovery connection as the client (joining member) and server (donor) negotiate the highest protocol version that they are both set up to support.

When the MySQL communication stack is in use for the group
(group_replication_communication_stack = MYSQL), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

The default is “TLSv1.2, TLSv1.3”. Ensure that the specified protocol versions are contiguous, with no versions numbers skipped from the middle of the sequence.

Important

• Support for the TLSv1 and TLSv1.1 connection protocols was deprecated in and later removed from MySQL Server in MySQL 8.0. See Removal of Support for the TLSv1 and TLSv1.1 Protocols for more information.

• Support for the TLSv1.3 protocol is available in MySQL 8.4, provided that MySQL Server was compiled using OpenSSL 1.1.1. The server checks the version of OpenSSL at startup, and if it is lower than 1.1.1, TLSv1.3 is removed from the default value for the system variable. In that case, the default is “TLSv1.2”.

• group_replication_recovery_use_ssl

Command-Line Format

--group-replication-recovery-use-ssl={OFF|ON}

System Variable

group_replication_recovery_use_ssl

Scope

Global

Dynamic

Yes

SET_VAR Hint Applies

No

Type

Boolean

Default Value

OFF

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

group_replication_recovery_use_ssl specifies whether Group Replication distributed recovery connections between group members should use SSL or not. See Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see Section 20.5.4.2, “Cloning for Distributed Recovery”), and you set this option to ON, Group Replication uses SSL for remote cloning operations as well as for state transfer from a donor’s binary log. If you set this option to OFF, Group Replication does not use SSL for remote cloning operations.

• group_replication_recovery_zstd_compression_level

Command-Line Format

--group-replication-recovery-zstd-compression-level=#
Group Replication System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>group_replication_recovery_zstd_compression_level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>22</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_zstd_compression_level` specifies the compression level to use for Group Replication distributed recovery connections that use the zstd compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default zstd compression level is 3. For distributed recovery connections that do not use zstd compression, this variable has no effect.

For more information, see Section 6.2.8, “Connection Compression Control”.

- `group_replication_single_primary_mode`

| Command-Line Format | --group-replication-single-primary-mode=[OFF|ON] |
|---------------------|-----------------------------------------------|
| System Variable     | group_replication_single_primary_mode         |
| Scope               | Global                                        |
| Dynamic             | Yes                                           |
| SET_VAR             | Hint Applies                                  |
| Type                | Boolean                                       |
| Default Value       | ON                                            |

**Note**

This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

`group_replication_single_primary_mode` instructs the group to pick a single server automatically to be the one that handles read/write workload. This server is the primary and all others are secondaries.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see Section 20.5.2, “Restarting a Group”.

If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match.
If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

Setting this variable **ON** causes any setting for `group_replication_auto_increment_increment` to be ignored.

Use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to change the value of this system variable while the group is still running. For more information, see Section 20.5.1.2, "Changing the Group Mode".

• **group_replication_ssl_mode**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-ssl-mode=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_ssl_mode</code></td>

<td><code>VERIFY_CA</code></td>
</tr>
<tr>
<td></td>
<td><code>VERIFY_IDENTITY</code></td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_ssl_mode` sets the security state of group communication connections between Group Replication members. The possible values are as follows:

- **DISABLED** Establish an unencrypted connection (the default).
- **REQUIRED** Establish a secure connection if the server supports secure connections.
- **VERIFY_CA** Like **REQUIRED**, but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.
- **VERIFY_IDENTITY** Like **VERIFY_CA**, but additionally verify that the server certificate matches the host to which the connection is attempted.

• **group_replication_start_on_boot**

| Command-Line Format              | `--group-replication-start-on-boot[={OFF|ON}]` |
|----------------------------------|-----------------------------------------------|
| System Variable                  | `group_replication_start_on_boot`             |
| Scope                            | Global                                        |
| Dynamic                          | Yes                                           |
| SET_VAR Hint Applies             | No                                            |
The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_start_on_boot` specifies whether the server should start Group Replication automatically (ON) or not (OFF) during server start. When you set this option to ON, Group Replication restarts automatically after a remote cloning operation is used for distributed recovery.

To start Group Replication automatically during server start, the user credentials for distributed recovery must be stored in the replication metadata repositories on the server using the `CHANGE REPLICATION SOURCE TO` statement. If you prefer to specify the user credentials on the `START GROUP_REPLICATION` statement, which stores the user credentials only in memory, ensure that `group_replication_start_on_boot` is set to OFF.

- `group_replication_tls_source`

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_tls_source` specifies the source of TLS material for Group Replication.

- `group_replication_transaction_size_limit`

This system variable should have the same value on all group members. The value of this system variable can be changed while Group Replication is running. The change takes effect immediately on the group member, and applies from the next transaction started on that member. During this
Group Replication System Variables

process, the value of the system variable is permitted to differ between group members, but some transactions might be rejected.

`group_replication_transaction_size_limit` configures the maximum transaction size in bytes which the replication group accepts. Transactions larger than this size are rolled back by the receiving member and are not broadcast to the group. Large transactions can cause problems for a replication group in terms of memory allocation, which can cause the system to slow down, or in terms of network bandwidth consumption, which can cause a member to be suspected of having failed because it is busy processing the large transaction.

When this system variable is set to 0 there is no limit to the size of transactions the group accepts. The default setting for this system variable is 150000000 bytes (approximately 143 MB). Adjust the value of this system variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size. The value of `group_replication_transaction_size_limit` should be the same on all group members. For further mitigation strategies for large transactions, see Section 20.3.2, “Group Replication Limitations”.

- `group_replication_unreachable_majority_timeout`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-unreachable-majority-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_unreachable_majority_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The current value of the system variable is read when an issue occurs that means the behavior is needed.

`group_replication_unreachable_majority_timeout` specifies a number of seconds for which members that suffer a network partition and cannot connect to the majority wait before leaving the group. In a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. While the majority group (S3,S4,S5) remains running, the minority group waits for the specified time for a network reconnection. For a detailed description of this scenario, see Section 20.7.8, “Handling a Network Partition and Loss of Quorum”.

By default, `group_replication_unreachable_majority_timeout` is set to 0, which means that members that find themselves in a minority due to a network partition wait forever to leave the group. If you set a timeout, when the specified time elapses, all pending transactions processed by the minority are rolled back, and the servers in the minority partition move to the ERROR state. If a member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it proceeds to make the specified number of attempts to rejoin the group while in super read only mode. If the member does not have any auto-rejoin attempts
specified, or if it has exhausted the specified number of attempts, it follows the action specified by the system variable `group_replication_exit_state_action`.

**Warning**

When you have a symmetric group, with just two members for example (S0,S2), if there is a network partition and there is no majority, after the configured timeout all members enter the `ERROR` state.

For more information on using this option, see Section 20.7.7.2, “Unreachable Majority Timeout”.

- `group_replication_view_change_uuid`

**Command-Line Format**

```bash
--group-replication-view-change-uuid=value
```

**Deprecated**

Yes

**System Variable**

`group_replication_view_change_uuid`

**Scope**

Global

**Dynamic**

Yes

**SET_VAR Hint Applies**

No

**Type**

String

**Default Value**

AUTOMATIC

**Note**

This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

`group_replication_view_change_uuid` specifies an alternative UUID to use as the UUID part of the identifier in the GTIDs for view change events generated by the group. The alternative UUID makes these internally generated transactions easy to distinguish from transactions received by the group from clients. This can be useful if your setup allows for failover between groups, and you need to identify and discard transactions that were specific to the backup group. The default value for this system variable is AUTOMATIC, meaning that the GTIDs for view change events use the group name specified by the `group_replication_group_name` system variable, as transactions from clients do. Group members at a release that does not have this system variable are treated as having the value AUTOMATIC.

The alternative UUID must be different from the group name specified by the `group_replication_group_name` system variable, and it must be different from the server UUID of any group member. It must also be different from any UUIDs used in the GTIDs that are applied to anonymous transactions on replication channels anywhere in this topology, using the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE_REPLICATION_SOURCE TO` statement.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see Section 20.5.2, “Restarting a Group”.

If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match.
If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

Logging of view change events is replaced by sharing of recovery metadata; thus, this variable is deprecated, and subject to removal in a future version of MySQL.

20.9.2 Group Replication Status Variables

This section describes the status variables providing information about Group Replication.

The status variables and their meanings are listed here:

- **Gr_control_messages_sent_count**
  Number of control messages sent by this member.

- **Gr_control_messages_sent_bytes_sum**
  Sum of the number of bytes used in control messages sent by this member; this is the on-the-wire size.

- **Gr_control_messages_sent_roundtrip_time_sum**
  Sum of the round-trip times in microseconds for control messages sent by this member; a round trip is measured between the sending and the delivery of the message on the sender. This should provide the time between sending and delivery of control messages for the majority of the members of the group, including the sender.

- **Gr_data_messages_sent_count**
  This is the number of transaction data messages sent by this member.

- **Gr_data_messages_sent_bytes_sum**
  Sum in bytes used by data messages sent by this member; this is the on-the-wire size.

- **Gr_data_messages_sent_roundtrip_time_sum**
  Sum of the round-trip times in microseconds for data messages sent by this member; a round trip is measured between the sending and the delivery of the message on the sender. This should provide the time between sending and delivery of data messages for the majority of the members of the group, including the sender.

- **Gr_transactions_consistency_after_termination_count**
  The number of transactions executed with `group_replication_consistency` equal to AFTER or BEFORE_AND_AFTER.

- **Gr_transactions_consistency_after_termination_time_sum**
  Sum of the time in microseconds between delivery of the transaction executed with `group_replication_consistency` equal to AFTER or BEFORE_AND_AFTER, and acknowledgement by the other group members that the transaction is prepared.

  This value does not include transaction send roundtrip time.

- **Gr_transactions_consistency_before_begin_count**
  Number of transactions executed with `group_replication_consistency` equal to BEFORE or BEFORE_AND_AFTER.

- **Gr_transactions_consistency_before_begin_time_sum**
Sum of the time in microseconds that the member waited until its group replication applier channel was consumed before executing the transaction with \texttt{group replication consistency} equal to \texttt{BEFORE} or \texttt{BEFORE AND AFTER}.

- \texttt{Gr\_transactions\_consistency\_after\_sync\_count}
  Number of transactions on secondaries that waited to start, while waiting for transactions from the primary with \texttt{group replication consistency} equal to \texttt{AFTER} or \texttt{BEFORE AND AFTER} to be committed.

- \texttt{Gr\_transactions\_consistency\_after\_sync\_time\_sum}
  Sum of the times in microseconds that transactions on secondaries waited on transactions from the primary with \texttt{group replication consistency} equal to \texttt{AFTER} or \texttt{BEFORE AND AFTER} to be committed, before starting.

- \texttt{Gr\_certification\_garbage\_collector\_count}
  The number of times certification garbage collection has been run.

- \texttt{Gr\_certification\_garbage\_collector\_time\_sum}
  Sum of the times in microseconds taken by certification garbage collection.

- \texttt{Gr\_all\_consensus\_proposals\_count}
  Sum of all proposals that were initiated and terminated on this node.

- \texttt{Gr\_empty\_consensus\_proposals\_count}
  Sum of all empty proposal rounds that were initiated and terminated on this node.

- \texttt{Gr\_consensus\_bytes\_sent\_sum}
  Sum of all socket-level bytes originating on this node that were sent to all (other) group nodes. More data is reported here than for sent messages, since they are multiplexed and sent to each member.

  For example, if we have a group with three members and we send a 100-byte message, this value accounts for 300 bytes, since we send 100 bytes to each node.

- \texttt{Gr\_all\_consensus\_time\_sum}
  The total elapsed time for all consensus rounds started and finished on this node. By comparing this value with \texttt{Gr\_all\_consensus\_proposals\_count}, we can determine whether a given consensus time has an upward trend, which may signal a problem.

- \texttt{Gr\_extended\_consensus\_count}
  The number of full 3-phase rounds that this node has initiated. If this number grows over time, it means that at least one node is having problems answering to proposals, either due to something it is running slow, or to network issues. Use this value together with the \texttt{count\_member\_failure\_suspicions} column of the Performance Schema \texttt{replication\_group\_communication\_information} table when diagnosing such issues.

- \texttt{Gr\_total\_messages\_sent\_count}
  The number of high-level messages sent by this node to the group. These are the messages received from the API for proposing to the group. The XCom batching mechanism batches these messages and proposes them all together. The value shown for this variable reflects the number of messages prior to batching.

- \texttt{Gr\_consensus\_bytes\_received\_sum}
Frequently Asked Questions

The sum of all socket-level bytes received from group nodes having this node as a destination.

- \texttt{Gr\_last\_consensus\_end\_timestamp}

The time when the last consensus proposal was approved, in a timestamp format. This can be an indicator whether the group is making slow progress, or has halted.

These status variables all have member scope since they reflect what the local member observes. They are reset on group bootstrap, joining of a new member, automatic rejoin of an existing member, and server restart.

20.10 Frequently Asked Questions

This section provides answers to frequently asked questions.

What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused. This limit has been identified from testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.

How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group. This address is configured by the \texttt{group\_replication\_local\_address} variable.

What is the \texttt{group\_replication\_bootstrap\_group} option used for?

The bootstrap flag instructs a member to create a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

How do I set credentials for the distributed recovery process?

You can set the user credentials permanently as the credentials for the \texttt{group\_replication\_recovery} channel, using a \texttt{CHANGE REPLICATION SOURCE TO} statement. You can specify them in the \texttt{START GROUP_REPLICATION} statement each time Group Replication is started.

User credentials set using \texttt{CHANGE REPLICATION SOURCE TO} are stored in plain text in the replication metadata repositories on the server, but user credentials specified on \texttt{START GROUP_REPLICATION} are saved in memory only, and are removed by a \texttt{STOP GROUP_REPLICATION} statement or server shutdown. Using \texttt{START GROUP_REPLICATION} to specify the user credentials therefore helps to secure the Group Replication servers against unauthorized access. However, this method is not compatible with starting Group Replication automatically, as specified by the \texttt{group\_replication\_start\_on\_boot} system variable. For more information, see Section 20.6.3.1, “Secure User Credentials for Distributed Recovery”.

Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.
Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

Can I deploy Group Replication across wide-area networks?

Yes, but the network connection between each member must be reliable and have suitable performance. Low latency, high bandwidth network connections are a requirement for optimal performance.

If network bandwidth alone is an issue, then Section 20.7.4, “Message Compression” can be used to lower the bandwidth required. However, if the network drops packets, leading to re-transmissions and higher end-to-end latency, throughput and latency are both negatively affected.

Warning

When the network round-trip time (RTT) between any group members is 5 seconds or more you could encounter problems as the built-in failure detection mechanism could be incorrectly triggered.

Do members automatically rejoin a group in case of temporary connectivity problems?

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a “long” connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

Two settings are available to increase the chances of a member remaining in or rejoining a group:

- `group_replication_member_expel_timeout` increases the time between the creation of a suspicion (which happens after an initial 5-second detection period) and the expulsion of the member. You can set a waiting period of up to 1 hour. A waiting period of 5 seconds is set by default.

- `group_replication_autorejoin_tries` makes a member try to rejoin the group after an expulsion or unreachable majority timeout. The member makes the specified number of auto-rejoin attempts five minutes apart. This feature is active by default; the member makes three auto-rejoin attempts.
When is a member excluded from a group?

If a server is expelled from the group and any auto-rejoin attempts do not succeed, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

When is a member excluded from a group?

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

What happens when one node is significantly lagging behind?

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group. Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to the your needs.

Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

Can I use Group Replication for sharding?

Group Replication is designed to provide highly available replica sets; data and writes are duplicated on each member in the group. For scaling beyond what a single system can provide, you need an orchestration and sharding framework built around a number of Group Replication sets, where each replica set maintains and manages a given shard or partition of your total dataset. This type of setup, often called a “sharded cluster”, allows you to scale reads and writes linearly and without limit.

How do I use Group Replication with SELinux?

If SELinux is enabled, which you can verify using `sestatus -v`, then you need to enable the use of the Group Replication communication port. See Setting the TCP Port Context for Group Replication.

How do I use Group Replication with iptables?

If `iptables` is enabled, then you need to open up the Group Replication port for communication between the machines. To see the current rules in place on each machine, issue `iptables -L`. Assuming the port configured is 33061, enable communication over the necessary port by issuing `iptables -A INPUT -p tcp --dport 33061 -j ACCEPT`.

How do I recover the relay log for a replication channel used by a group member?

The replication channels used by Group Replication behave in the same way as replication channels used in asynchronous source to replica replication, and as such rely on the relay log. In the event of a change of the `relay_log` variable, or when the option is not set and the host name changes, there is a chance of errors. See Section 19.2.4.1, “The Relay Log” for a recovery procedure in this situation. Alternatively, another way of fixing the issue specifically in Group Replication is to issue a `STOP`
Why does Group Replication use two bind addresses?

Group Replication uses two bind addresses in order to split network traffic between the SQL address, used by clients to communicate with the member, and the `group_replication_local_address`, used internally by the group members to communicate. For example, assume a server with two network interfaces assigned to the network addresses 203.0.113.1 and 198.51.100.179. In such a situation you could use 203.0.113.1:33061 for the internal group network address by setting `group_replication_local_address=203.0.113.1:33061`. Then you could use 198.51.100.179 for hostname and 3306 for the port. Client SQL applications would then connect to the member at 198.51.100.179:3306. This enables you to configure different rules on the different networks. Similarly, the internal group communication can be separated from the network connection used for client applications, for increased security.

How does Group Replication use network addresses and hostnames?

Group Replication uses network connections between members and therefore its functionality is directly impacted by how you configure hostnames and ports. For example, Group Replication's distributed recovery process creates a connection to an existing group member using the server's hostname and port. When a member joins a group it receives the group membership information, using the network address information that is listed at `performance_schema.replication_group_members`. One of the members listed in that table is selected as the donor of the missing data from the group to the joining member.

This means that any value you configure using a hostname, such as the SQL network address or the group seeds address, must be a fully qualified name and resolvable by each member of the group. You can ensure this for example through DNS, or correctly configured /etc/hosts files, or other local processes. If you want to configure the `MEMBER_HOST` value on a server, specify it using the `--report-host` option on the server before joining it to the group.

### Important

The assigned value is used directly and is not affected by the `skip_name_resolve` system variable.

To configure `MEMBER_PORT` on a server, specify it using the `report_port` system variable.

Why did the auto increment setting on the server change?

When Group Replication is started on a server, the value of `auto_increment_increment` is changed to the value of `group_replication_auto_increment_increment`, which defaults to 7, and the value of `auto_increment_offset` is changed to the server ID. The changes are reverted when Group Replication is stopped. These settings avoid the selection of duplicate auto-increment values for writes on group members, which causes rollback of transactions. The default auto increment value of 7 for Group Replication represents a balance between the number of usable values and the permitted maximum size of a replication group (9 members).

The changes are made and reverted only if `auto_increment_increment` and `auto_increment_offset` each has its default value (1 in both cases). If their values have already been modified from the default, Group Replication does not alter them. The system variables are also not modified when Group Replication is in single-primary mode, where only one server writes.

How do I find the primary?

If the group is operating in single-primary mode, it can be useful to find out which member is the primary. See [Finding the Primary](#)
Chapter 21 MySQL Shell

MySQL Shell is an advanced client and code editor for MySQL Server. In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL. MySQL Shell is a component that you can install separately.

The following discussion briefly describes MySQL Shell's capabilities. For more information, see the MySQL Shell manual, available at https://dev.mysql.com/doc/mysql-shell/en/.

MySQL Shell includes the following APIs implemented in JavaScript and Python which you can use to develop code that interacts with MySQL.

- The X DevAPI enables developers to work with both relational and document data when MySQL Shell is connected to a MySQL server using the X Protocol. This enables you to use MySQL as a Document Store, sometimes referred to as “using NoSQL”. For more information, see Chapter 22, Using MySQL as a Document Store. For documentation on the concepts and usage of X DevAPI, which is implemented in MySQL Shell, see X DevAPI User Guide.

- The AdminAPI enables database administrators to work with InnoDB Cluster, which provides an integrated solution for high availability and scalability using InnoDB based MySQL databases, without requiring advanced MySQL expertise. The AdminAPI also includes support for InnoDB ReplicaSet, which enables you to administer a set of MySQL instances running asynchronous GTID-based replication in a similar way to InnoDB Cluster. Additionally, the AdminAPI makes administration of MySQL Router easier, including integration with both InnoDB Cluster and InnoDB ReplicaSet. See MySQL AdminAPI.

MySQL Shell is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features at low cost.

This chapter introduces an alternative way of working with MySQL as a document store, sometimes referred to as “using NoSQL”. If your intention is to use MySQL in a traditional (SQL) way, this chapter is probably not relevant to you.

Traditionally, relational databases such as MySQL have usually required a schema to be defined before documents can be stored. The features described in this section enable you to use MySQL as a document store, which is a schema-less, and therefore schema-flexible, storage system for documents. For example, when you create documents describing products, you do not need to know and define all possible attributes of any products before storing and operating with the documents. This differs from working with a relational database and storing products in a table, when all columns of the table must be known and defined before adding any products to the database. The features described in this chapter enable you to choose how you configure MySQL, using only the document store model, or combining the flexibility of the document store model with the power of the relational model.

To use MySQL as a document store, you use the following server features:

- X Plugin enables MySQL Server to communicate with clients using X Protocol, which is a prerequisite for using MySQL as a document store. X Plugin is enabled by default in MySQL Server as of MySQL 8.4. For instructions to verify X Plugin installation and to configure and monitor X Plugin, see Section 22.5, “X Plugin”.

- X Protocol supports both CRUD and SQL operations, authentication via SASL, allows streaming (pipelining) of commands and is extensible on the protocol and the message layer. Clients compatible with X Protocol include MySQL Shell and MySQL 8.4 Connectors.

- Clients that communicate with a MySQL Server using X Protocol can use X DevAPI to develop applications. X DevAPI offers a modern programming interface with a simple yet powerful design which provides support for established industry standard concepts. This chapter explains how to get started using either the JavaScript or Python implementation of X DevAPI in MySQL Shell as a client. See X DevAPI User Guide for in-depth tutorials on using X DevAPI.
22.1 Interfaces to a MySQL Document Store

To work with MySQL as a document store, you use dedicated components and a choice of clients that support communicating with the MySQL server to develop document based applications.

- The following MySQL products support X Protocol and enable you to use X DevAPI in your chosen language to develop applications that communicate with a MySQL Server functioning as a document store:
  - MySQL Shell (which provides implementations of X DevAPI in JavaScript and Python)
  - Connector/C++
  - Connector/J
  - Connector/Node.js
  - Connector/NET
  - Connector/Python

- MySQL Shell is an interactive interface to MySQL supporting JavaScript, Python, or SQL modes. You can use MySQL Shell to prototype applications, execute queries and update data. Installing MySQL Shell has instructions to download and install MySQL Shell.

- The quick-start guides (tutorials) in this chapter help you to get started using MySQL Shell with MySQL as a document store.

  The quick-start guide for Python is here: Section 22.4, “Python Quick-Start Guide: MySQL Shell for Document Store”.

- The MySQL Shell User Guide at MySQL Shell 8.4.0 provides detailed information about configuring and using MySQL Shell.

22.2 Document Store Concepts

This section explains the concepts introduced as part of using MySQL as a document store.

- JSON Document
- Collection
- CRUD Operations

JSON Document

A JSON document is a data structure composed of key-value pairs and is the fundamental structure for using MySQL as document store. For example, the world_x schema (installed later in this chapter) contains this document:

```json
{
  "GNP": 4834,
  "_id": "00005de917d800000000000000000023",
  "Code": "BWA",
  "Name": "Botswana",
  "IndepYear": 1966,
  "geography": {
    "Region": "Southern Africa",
    "Continent": "Africa",
  }
}
```
This document shows that the values of keys can be simple data types, such as integers or strings, but can also contain other documents, arrays, and lists of documents. For example, the `geography` key's value consists of multiple key-value pairs. A JSON document is represented internally using the MySQL binary JSON object, through the JSON MySQL datatype.

The most important differences between a document and the tables known from traditional relational databases are that the structure of a document does not have to be defined in advance, and a collection can contain multiple documents with different structures. Relational tables on the other hand require that their structure be defined, and all rows in the table must contain the same columns.

### Collection

A collection is a container that is used to store JSON documents in a MySQL database. Applications usually run operations against a collection of documents, for example to find a specific document.

### CRUD Operations

The four basic operations that can be issued against a collection are Create, Read, Update and Delete (CRUD). In terms of MySQL this means:

- Create a new document (insertion or addition)
- Read one or more documents (queries)
- Update one or more documents
- Delete one or more documents

### 22.3 JavaScript Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` example schema.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.4, and MySQL Shell to use as the client. MySQL Shell 8.4.0 provides more in-depth information about MySQL Shell. The Document Store is accessed using X DevAPI, and MySQL Shell provides this API in both JavaScript and Python.

### Related Information

- MySQL Shell 8.4.0 provides more in-depth information about MySQL Shell.
• See Installing MySQL Shell and Section 22.5, “X Plugin” for more information about the tools used in this quick-start guide.

• X DevAPI User Guide provides more examples of using X DevAPI to develop applications which use Document Store.

• A Python quick-start guide is also available.

22.3.1 MySQL Shell

This quick-start guide assumes a certain level of familiarity with MySQL Shell. The following section is a high level overview, see the MySQL Shell documentation for more information. MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. You need to know the address of the MySQL server instance you plan to connect to. To be able to use the instance as a Document Store, the server instance must have X Plugin installed and you should connect to the server using X Protocol. For example to connect to the instance `ds1.example.com` on the default X Protocol port of 3306 use the network string `user@ds1.example.com:33060`.

Tip

If you connect to the instance using classic MySQL protocol, for example by using the default port of 3306 instead of the `mysqlx_port`, you cannot use the Document Store functionality shown in this tutorial. For example the `db` global object is not populated. To use the Document Store, always connect using X Protocol.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh user@ds1.example.com:33060/world_x
```

Alternatively, if MySQL Shell is already running use the `\connect` command by issuing:

```
\connect user@ds1.example.com:33060/world_x
```

You need to specify the address of the MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

• `user` represents the user name of your MySQL account.

• `ds1.example.com` is the hostname of the server instance running MySQL. Replace this with the hostname of the MySQL server instance you are using as a Document Store.

• The default schema for this session is `world_x`. For instructions on setting up the `world_x` schema, see Section 22.3.2, “Download and Import world_x Database”.

For more information, see Section 6.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”.

Once MySQL Shell opens, the `mysql-js>` prompt indicates that the active language for this session is JavaScript.

```
mysql-js>
```

MySQL Shell supports input-line editing as follows:

• `left-arrow` and `right-arrow` keys move horizontally within the current input line.
Download and Import world_x Database

- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** sends the current input line to the server.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-js> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, issue:

```
mysql-js> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, issue the following command:

```
mysql-js> \quit
```

Related Information

- See Interactive Code Execution for an explanation of how interactive code execution works in MySQL Shell.
- See Getting Started with MySQL Shell to learn about session and connection alternatives.

22.3.2 Download and Import world_x Database

As part of this quick-start guide, an example schema is provided which is referred to as the `world_x` schema. Many of the examples demonstrate Document Store functionality using this schema. Start your MySQL server so that you can load the `world_x` schema, then follow these steps:

1. Download `world_x-db.zip`.
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Import the `world_x.sql` file to your server. You can either:
   - Start MySQL Shell in SQL mode and import the file by issuing:
     ```
     mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
     Enter password: ****
     ```
   - Set MySQL Shell to SQL mode while it is running and source the schema file by issuing:
     ```
     mysql-js> \sql
     Switching to SQL mode... Commands end with ;
     \source /tmp/world_x-db/world_x.sql
     ```

Replace `/tmp/` with the path to the `world_x.sql` file on your system. Enter your password if prompted. A non-root account can be used as long as the account has privileges to create new schemas.

The world_x Schema
The *world_x* example schema contains the following JSON collection and relational tables:

- **Collection**
  - *countryinfo*: Information about countries in the world.

- **Tables**
  - *country*: Minimal information about countries of the world.
  - *city*: Information about some of the cities in those countries.
  - *countrylanguage*: Languages spoken in each country.

**Related Information**

- [MySQL Shell Sessions](#) explains session types.

**22.3.3 Documents and Collections**

When you are using MySQL as a Document Store, collections are containers within a schema that you can create, list, and drop. Collections contain JSON documents that you can add, find, update, and remove.

The examples in this section use the *countryinfo* collection in the *world_x* schema. For instructions on setting up the *world_x* schema, see Section 22.3.2, “Download and Import world_x Database”.

**Documents**

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for JavaScript:
  ```javascript
  {field1: "value", field2 : 10, "field 3": null}
  ```

  An array of documents consists of a set of documents separated by commas and enclosed within [ and ] characters.

- Simple array of documents for JavaScript:
  ```javascript
  [{"Name": "Aruba", "Code": "ABW"}, {"Name": "Angola", "Code": "AGO"}]
  ```

MySQL supports the following JavaScript value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- null
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

**Collections**

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.
Documents and Collections

The term schema is equivalent to a database, which means a group of database objects as opposed to a relational schema, used to enforce structure and constraints over data. A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

<table>
<thead>
<tr>
<th>Object form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db</code></td>
<td><code>db</code> is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the <code>db</code> variable.</td>
</tr>
<tr>
<td><code>db.getCollections()</code></td>
<td><code>db.getCollections()</code> returns a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.</td>
</tr>
</tbody>
</table>

- Basic operations scoped by collections include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.add()</code></td>
<td>The <code>add()</code> method inserts one document or a list of documents into the named collection.</td>
</tr>
<tr>
<td><code>db.name.find()</code></td>
<td>The <code>find()</code> method returns some or all documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.modify()</code></td>
<td>The <code>modify()</code> method updates documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.remove()</code></td>
<td>The <code>remove()</code> method deletes one document or a list of documents from the named collection.</td>
</tr>
</tbody>
</table>

Related Information

- See [Working with Collections](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.

### 22.3.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

**Confirm the Schema**

To show the value that is assigned to the schema variable, issue:

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```
mysql-js> \use world_x
```

**Create a Collection**

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` schema.

```
mysql-js> db.createCollection("flags")
```
The method returns a collection object.

```
<Collection:flags>
```

**List Collections**

To display all collections in the `world_x` schema, use the `db` object's `getCollections()` method. Collections returned by the server you are currently connected to appear between brackets.

```
mysql-js> db.getCollections()
[  
  <Collection:countryinfo>,
  <Collection:flags>
]
```

**Drop a Collection**

To drop an existing collection from a schema, use the `db` object's `dropCollection()` method. For example, to drop the `flags` collection from the current schema, issue:

```
mysql-js> db.dropCollection("flags")
```

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a schema.

**Related Information**

- See [Collection Objects](#) for more examples.

**22.3.3.2 Working with Collections**

To work with the collections in a schema, use the `db` global object to access the current schema. In this example we are using the `world_x` schema imported previously, and the `countryinfo` collection. Therefore, the format of the operations you issue is `db.collection_name.operation`, where `collection_name` is the name of the collection which the operation is executed against. In the following examples, the operations are executed against the `countryinfo` collection.

**Add a Document**

Use the `add()` method to insert one document or a list of documents into an existing collection. Insert the following document into the `countryinfo` collection. As this is multi-line content, press Enter twice to insert the document.

```
mysql-js> db.countryinfo.add(
{  
    GNP: 6.6,
    IndepYear: 1967,
    Name: "Sealand",
    Code: "SEA",
    demographics: {
        LifeExpectancy: 79,
        Population: 27
    },
    geography: {
        Continent: "Europe",
        Region: "British Islands",
        SurfaceArea: 193
    },
    government: {
        GovernmentForm: "Monarchy",
        HeadOfState: "Michael Bates"
    }
}
)
```

The method returns the status of the operation. You can verify the operation by searching for the document. For example:
mysql-js> db.countryinfo.find("Name = 'Sealand'")
{
    "GNP": 0.6,
    "_id": "000005e2ff4af00000000000000000f4",
    "Name": "Sealand",
    "Code": "SEA",
    "IndepYear": 1967,
    "geography": {
        "Region": "British Islands",
        "Continent": "Europe",
        "SurfaceArea": 193
    },
    "government": {
        "HeadOfState": "Michael Bates",
        "GovernmentForm": "Monarchy"
    },
    "demographics": {
        "Population": 27,
        "LifeExpectancy": 79
    }
}

Note that in addition to the fields specified when the document was added, there is one more field, the _id. Each document requires an identifier field called _id. The value of the _id field must be unique among all documents in the same collection. Document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an _id value. MySQL sets an _id value if the document does not contain the _id field. For more information, see Understanding Document IDs.

Related Information

- See CollectionAddFunction for the full syntax definition.
- See Understanding Document IDs.

22.3.3.3 Find Documents

You can use the find() method to query for and return documents from a collection in a schema. MySQL Shell provides additional methods to use with the find() method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: OR (| |), AND (&&), XOR, IS, NOT, BETWEEN, IN, LIKE, ! =, <>, > , >=, <, <=, |, | < | > |, +, *, /, ~, and %.

Find All Documents in a Collection

To return all documents in a collection, use the find() method without specifying search conditions. For example, the following operation returns all documents in the countryinfo collection.

mysql-js> db.countryinfo.find()
[
    {
        "GNP": 828,
        "Code": "ABW",
        "Name": "Aruba",
        "IndepYear": null,
        "geography": {
            "Continent": "North America",
            "Region": "Caribbean",
            "SurfaceArea": 193
        },
        "government": {
            "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
            "HeadOfState": "Beatrix"
        },
        "demographics": {
            "LifeExpectancy": 78.4000015258789,
            "Population": 103000
        }
    }
]
The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

Empty set (0.00 sec)

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional MySQL. You must enclose all expressions in quotes. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the `Name` field and a value we know is in a document. The following example returns a single document:

```
mysql-js> db.countryinfo.find("Name = 'Australia'")
```

```
[ { 
  "GNP": 351182,
  "Code": "AUS",
  "Name": "Australia",
  "IndepYear": 1901,
  "geography": { 
    "Continent": "Oceania",
    "Region": "Australia and New Zealand",
    "SurfaceArea": 7741220
  },
  "government": { 
    "GovernmentForm": "Constitutional Monarchy, Federation",
    "HeadOfState": "Elisabeth II"
  }
},
```

The following example searches for all countries that have a GNP higher than $500 billion. The `countryinfo` collection measures GNP in units of million.

```
mysql-js> db.countryinfo.find("GNP > 500000")
```

```
[output removed]
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than $30000. Search conditions can include arithmetic operators and most MySQL functions.

```
mysql-js> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
```

```
[output removed]
```

Note

Seven documents in the `countryinfo` collection have a population value of zero. Therefore warning messages appear at the end of the output.
You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then use the `bind(placeholder, value)` method as follows:

```
mysql-js> db.countryinfo.find("Name = :country").bind("country", "Italy")
{  
  "GNP": 1161755, 
  "_id": "00005de917d80000000000006a", 
  "Code": "ITA", 
  "Name": "Italy", 
  "Airports": [], 
  "IndepYear": 1861, 
  "geography": { 
    "Region": "Southern Europe", 
    "Continent": "Europe", 
    "SurfaceArea": 301316 
  }, 
  "government": { 
    "HeadOfState": "Carlo Azeglio Ciampi", 
    "GovernmentForm": "Republic" 
  }, 
  "demographics": { 
    "Population": 57680000, 
    "LifeExpectancy": 79 
  } 
}
1 document in set (0.01 sec)
```

**Tip**

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```
mysql-js> var myFind = db.countryinfo.find("Name = :country")
mysql-js> myFind.bind('country', 'France')
{  
  "GNP": 1424285, 
  "_id": "00005de917d800000000000048", 
  "Code": "FRA", 
  "Name": "France", 
  "IndepYear": 843, 
  "geography": { 
    "Region": "Western Europe", 
    "Continent": "Europe", 
    "SurfaceArea": 551500 
  }, 
  "government": { 
    "HeadOfState": "Jacques Chirac", 
    "GovernmentForm": "Republic"  
  } 
}
```
Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```javascript
db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
```

```javascript
[  
  {  
    "GNP": 8510700,  
    "Name": "United States"  
  }
]
1 document in set (0.00 sec)
```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```javascript
db.countryinfo.find().fields(  
  mysqlx.expr("{"Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}"").limit(2)
)
```

```javascript
{  
  "Name": "ARUBA",  
  "GNPPerCapita": 8038.834951456311
}

{  
  "Name": "AFGHANISTAN",  
  "GNPPerCapita": 263.0281690140845
}
```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.
To specify the number of documents included in a result set, append the \texttt{limit()} method with a value to the \texttt{find()} method. The following query returns the first five documents in the \texttt{countryinfo} collection.

\begin{verbatim}
mysql-js> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)
\end{verbatim}

To specify an order for the results, append the \texttt{sort()} method to the \texttt{find()} method. Pass to the \texttt{sort()} method a list of one or more fields to sort by and, optionally, the descending (\texttt{desc}) or ascending (\texttt{asc}) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the IndepYear field and then returns the first eight documents in descending order.

\begin{verbatim}
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
\end{verbatim}

By default, the \texttt{limit()} method starts from the first document in the collection. You can use the \texttt{skip()} method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the \texttt{skip()} method a value of 1.

\begin{verbatim}
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
\end{verbatim}

### Related Information

- The \texttt{MySQL Reference Manual} provides detailed documentation on functions and operators.
- See \texttt{CollectionFindFunction} for the full syntax definition.

### 22.3.3.4 Modify Documents

You can use the \texttt{modify()} method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the \texttt{modify()} method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

#### Set and Unset Document Fields

The \texttt{modify()} method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the \texttt{modify()} method uses the search condition to identify the document to change and then the \texttt{set()} method replaces two values within the nested demographics object.

\begin{verbatim}
mysql-js> db.countryinfo.modify("Code = 'SEA'").set("demographics", {"LifeExpectancy": 78, "Population": 28})
\end{verbatim}

After you modify a document, use the \texttt{find()} method to verify the change.

To remove content from a document, use the \texttt{modify()} and \texttt{unset()} methods. For example, the following query removes the GNP from a document that matches the search condition.

\begin{verbatim}
mysql-js> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
\end{verbatim}

Use the \texttt{find()} method to verify the change.

\begin{verbatim}
mysql-js> db.countryinfo.find("Name = 'Sealand'")
\end{verbatim}
Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `arrayAppend()`, `arrayInsert()`, or `arrayDelete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new Airports field in all documents.

```javascript
mysql-js> db.countryinfo.modify("true").set("Airports", [])
```

With the Airports field added, the next example uses the `arrayAppend()` method to add a new airport to one of the documents. `$.Airports` in the following example represents the Airports field of the current document.

```javascript
mysql-js> db.countryinfo.modify("Name = 'France'").arrayAppend("$.Airports", "ORY")
```

Use `find()` to see the change.

```javascript
mysql-js> db.countryinfo.find("Name = 'France'")
```

```javascript
{
  "GNP": 1424285,
  "_id": "00005e2ff4af0000000000000000f4",
  "Name": "Sealand",
  "Code": "SEA",
  "IndepYear": 1967,
  "geography": {
    "Region": "British Islands",
    "Continent": "Europe",
    "SurfaceArea": 193
  },
  "government": {
    "HeadOfState": "Michael Bates",
    "GovernmentForm": "Monarchy"
  },
  "demographics": {
    "Population": 27,
    "LifeExpectancy": 79
  }
}```
To insert an element at a different position in the array, use the `arrayInsert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```javascript
mysql-js> db.countryinfo.modify("Name = 'France'").arrayInsert("$.Airports[0]", "CDG")
```

To delete an element from the array, you must pass to the `arrayDelete()` method the index of the element to be deleted.

```javascript
mysql-js> db.countryinfo.modify("Name = 'France'").arrayDelete("$.Airports[1]")
```

### Related Information

- See [CollectionModifyFunction](https://dev.mysql.com/doc/refman/8.0/en/json.html) for the full syntax definition.

#### 22.3.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a schema. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

### Remove Documents Using Conditions

The following example passes a search condition to the `remove()` method. All documents matching the condition are removed from the `countryinfo` collection. In this example, one document matches the condition.

```javascript
mysql-js> db.countryinfo.remove("Code = 'SEA'")
```

### Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```javascript
mysql-js> db.countryinfo.remove("true").limit(1)
```

### Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```javascript
mysql-js> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
```

### Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying a search condition.

⚠️ **Caution**

Use care when you remove documents without specifying a search condition. This action deletes all documents from the collection.

Alternatively, use the `db.drop_collection('countryinfo')` operation to delete the `countryinfo` collection.

### Related Information

- See [CollectionRemoveFunction](https://dev.mysql.com/doc/refman/8.0/en/json.html) for the full syntax definition.
- See Section 22.3.2, “Download and Import world_x Database” for instructions to recreate the `world_x` schema.
Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query performs better with an index on the Population field:

```sql
db.countryinfo.find("demographics.Population < 100")
```

The `createIndex()` method creates an index that you can define with a JSON document that specifies which fields to use. This section is a high level overview of indexing. For more information see Indexing Collections.

### Add a Nonunique Index

To create a nonunique index, pass an index name and the index information to the `createIndex()` method. Duplicate index names are prohibited.

The following example specifies an index named `popul`, defined against the `Population` field from the `demographics` object, indexed as an `Integer` numeric value. The final parameter indicates whether the field should require the `NOT NULL` constraint. If the value is `false`, the field can contain `NULL` values. The index information is a JSON document with details of one or more fields to include in the index. Each field definition must include the full document path to the field, and specify the type of the field.

```sql
db.countryinfo.createIndex("popul", {fields: [{field: '$.demographics.Population', type: 'INTEGER'}]})
```

Here, the index is created using an integer numeric value. Further options are available, including options for use with GeoJSON data. You can also specify the type of index, which has been omitted here because the default type "index" is appropriate.

### Add a Unique Index

To create a unique index, pass an index name, the index definition, and the index type "unique" to the `createIndex()` method. This example shows a unique index created on the country name ("Name"), which is another common field in the `countryinfo` collection to index. In the index field description, "TEXT(40)" represents the number of characters to index, and "required": True specifies that the field is required to exist in the document.

```sql
db.countryinfo.createIndex("name", {fields: [{field: "$.Name", type: "TEXT(40)", required: true}], unique: true})
```

### Drop an Index

To drop an index, pass the name of the index to drop to the `dropIndex()` method. For example, you can drop the “popul” index as follows:

```sql
db.countryinfo.dropIndex("popul")
```

### Related Information

- See Indexing Collections for more information.
- See Defining an Index for more information on the JSON document that defines an index.
- See Collection Index Management Functions for the full syntax definition.
You can also use X DevAPI to work with relational tables. In MySQL, each relational table is associated with a particular storage engine. The examples in this section use InnoDB tables in the `world_x` schema.

**Confirm the Schema**

To show the schema that is assigned to the `db` global variable, issue `db`.

```javascript
mysql-js> db
<Schema:world_x>
```

If the returned value is not `Schema:world_x`, set the `db` variable as follows:

```javascript
mysql-js> \use world_x
Schema 'world_x' accessible through db.
```

**Show All Tables**

To display all relational tables in the `world_x` schema, use the `getTables()` method on the `db` object.

```javascript
mysql-js> db.getTables()
{
  "city": <Table:city>,
  "country": <Table:country>,
  "countrylanguage": <Table:countrylanguage>
}
```

**Basic Table Operations**

Basic operations scoped by tables include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.insert()</code></td>
<td>The <code>insert()</code> method inserts one or more records into the named table.</td>
</tr>
<tr>
<td><code>db.name.select()</code></td>
<td>The <code>select()</code> method returns some or all records in the named table.</td>
</tr>
<tr>
<td><code>db.name.update()</code></td>
<td>The <code>update()</code> method updates records in the named table.</td>
</tr>
<tr>
<td><code>db.name.delete()</code></td>
<td>The <code>delete()</code> method deletes one or more records from the named table.</td>
</tr>
</tbody>
</table>

**Related Information**

- See [Working with Relational Tables](#) for more information.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 22.3.2, “Download and Import world_x Database”](#) for instructions on setting up the `world_x` Schema sample.

**22.3.4.1 Insert Records into Tables**

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

**Insert a Complete Record**

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column in the table. For example, to add a new record to the city table in the `world_x` schema, insert the following record and press Enter twice.
The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

**Insert a Partial Record**

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-j> db.city.insert("ID", "Name", "CountryCode").values(
None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

**Related Information**

- See TableInsertFunction for the full syntax definition.

### 22.3.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: **OR** ( || ), **AND** ( && ), **XOR** ( ^ ), **IS** ( = ), **NOT** ( ! ), **BETWEEN** ( BETWEEN, IN, LIKE, !=, <> , >=, <, <=, |, <<, >>, +, *, /, ~, and %).

**Select All Records**

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

```
mysql-j> db.city.select()
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

### Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-j> db.city.select(["Name", "CountryCode"])
```
To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```javascript
mysql-js> db.city.select(["Name", "CountryCode"]).where("Name like 'Z\%'")
```

```
+-------------------+-------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zaanstad</td>
<td>NLD</td>
</tr>
<tr>
<td>Zoetermeer</td>
<td>NLD</td>
</tr>
<tr>
<td>Zwolle</td>
<td>NLD</td>
</tr>
<tr>
<td>Zenica</td>
<td>BIH</td>
</tr>
<tr>
<td>Zagagig</td>
<td>EGY</td>
</tr>
<tr>
<td>Zaragoza</td>
<td>ESP</td>
</tr>
<tr>
<td>Zamboanga</td>
<td>PHL</td>
</tr>
<tr>
<td>Zahedan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zanjian</td>
<td>IRN</td>
</tr>
<tr>
<td>Zabol</td>
<td>IRN</td>
</tr>
<tr>
<td>Zama</td>
<td>JPN</td>
</tr>
<tr>
<td>Zhezqazghan</td>
<td>KAZ</td>
</tr>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
</tbody>
</table>
+-------------------+-------------+
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using "Name = 'Z\%' " as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```javascript
mysql-js> db.city.select(["Name", "CountryCode"]).where("Name like :name").bind("name", "Z\%")
```

**Tip**

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

**Project Results**

To issue a query using the **AND** operator, add the operator between search conditions in the `where()` method.

```javascript
mysql-js> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%' and CountryCode = 'CHN'")
```

```
+----------------+-------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>
+----------------+-------------+
3725 rows in set (0.00 sec)
```
To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of **AND** and **OR** operators.

```sql
mysql-js> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')")
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiang</td>
<td>CHN</td>
</tr>
<tr>
<td>Zigong</td>
<td>CHN</td>
</tr>
<tr>
<td>Zaozhuang</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zhangjiagang</td>
<td>CHN</td>
</tr>
</tbody>
</table>
```

22 rows in set (0.01 sec)

**Limit, Order, and Offset Results**

You can apply the `limit()`, `orderBy()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```sql
mysql-js> db.country.select(["Code", "Name"]).limit(5)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABW</td>
<td>Aruba</td>
</tr>
<tr>
<td>AFG</td>
<td>Afghanistan</td>
</tr>
<tr>
<td>AGO</td>
<td>Angola</td>
</tr>
<tr>
<td>AIA</td>
<td>Anguilla</td>
</tr>
<tr>
<td>ALB</td>
<td>Albania</td>
</tr>
</tbody>
</table>
```

5 rows in set (0.00 sec)

To specify an order for the results, append the `orderBy()` method to the `select()` method. Pass to the `orderBy()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order.

```sql
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZWE</td>
<td>Zimbabwe</td>
</tr>
<tr>
<td>ZMB</td>
<td>Zambia</td>
</tr>
<tr>
<td>YUG</td>
<td>Yugoslavia</td>
</tr>
</tbody>
</table>
```

3 rows in set (0.00 sec)
By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```javascript
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3).offset(1)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZMB</td>
<td>Zambia</td>
</tr>
<tr>
<td>YUG</td>
<td>Yugoslavia</td>
</tr>
<tr>
<td>YEM</td>
<td>Yemen</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

**Related Information**

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [TableSelectFunction](#) for the full syntax definition.

### 22.3.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```javascript
mysql-js> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
```

Use the `select()` method to verify the change.

```javascript
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
```

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>CountryCode</th>
<th>District</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>1891</td>
<td>Beijing</td>
<td>CHN</td>
<td>Peking</td>
<td>{&quot;Population&quot;: 7472000}</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

**Related Information**

- See [TableUpdateFunction](#) for the full syntax definition.

### 22.3.4.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

**Delete Records Using Conditions**

The following example passes search conditions to the `delete()` method. All records matching the condition are deleted from the city table. In this example, one record matches the condition.

```javascript
mysql-js> db.city.delete().where("Name = 'Olympia'")
```

**Delete the First Record**

To delete the first record in the city table, use the `limit()` method with a value of 1.

```javascript
mysql-js> db.city.delete().limit(1)
```
Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

❗ Caution

Use care when you delete records without specifying a search condition; doing so deletes all records from the table.

Drop a Table

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the `citytest` table from the `world_x` database, issue:

```bash
mysql-js> session.dropCollection("world_x", "citytest")
```

Related Information

- See [TableDeleteFunction](#) for the full syntax definition.
- See [Section 22.3.2, “Download and Import world_x Database”](#) for instructions to recreate the `world_x` database.

22.3.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native JSON data type.

Examples in this section use the city table in the `world_x` schema.

city Table Description

The city table has five columns (or fields).

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>int(11)</td>
<td>NO</td>
<td>PRI</td>
<td>null</td>
<td>auto_increment</td>
</tr>
<tr>
<td>Name</td>
<td>char(35)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CountryCode</td>
<td>char(3)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>District</td>
<td>char(20)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Info</td>
<td>json</td>
<td>YES</td>
<td></td>
<td>null</td>
<td></td>
</tr>
</tbody>
</table>

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```bash
mysql-js> db.city.insert().values(
None, "San Francisco", "USA", "California", '{"Population":830000}')
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```bash
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"])
```
This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` example schema.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.4, and MySQL Shell to use as the client. MySQL Shell includes X DevAPI, implemented in both JavaScript and Python, which enables you to connect to the MySQL server instance using X Protocol and use the server as a Document Store.

### Related Information

- See [Working with Relational Tables and Documents](#) for more information.
- See [Section 13.5, “The JSON Data Type”](#) for a detailed description of the data type.

### 22.4 Python Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide assumes a certain level of familiarity with MySQL Shell. The following section is a high level overview, see the MySQL Shell documentation for more information. MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode.

#### Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. You need to know the address of the MySQL server instance you plan to connect to. To be able to use the instance as a Document Store, the server instance must have X Plugin installed and you should...
connect to the server using X Protocol. For example to connect to the instance \texttt{ds1.example.com} on the default X Protocol port of 33060 use the network string \texttt{user@ds1.example.com:33060}.

\textbf{Tip}

If you connect to the instance using classic MySQL protocol, for example by using the default port of 3306 instead of the \texttt{mysqlx_port}, you cannot use the Document Store functionality shown in this tutorial. For example the \texttt{db} global object is not populated. To use the Document Store, always connect using X Protocol.

If MySQL Shell is not already running, open a terminal window and issue:

\texttt{mysqlsh user@ds1.example.com:33060/world_x}

Alternatively, if MySQL Shell is already running use the \texttt{\connect} command by issuing:

\texttt{\connect user@ds1.example.com:33060/world_x}

You need to specify the address of the MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- \texttt{user} represents the user name of your MySQL account.
- \texttt{ds1.example.com} is the hostname of the server instance running MySQL. Replace this with the hostname of the MySQL server instance you are using as a Document Store.
- The default schema for this session is \texttt{world_x}. For instructions on setting up the \texttt{world_x} schema, see Section 22.4.2, “Download and Import world_x Database”.

For more information, see Section 6.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”.

Once MySQL Shell opens, the \texttt{mysql-js>} prompt indicates that the active language for this session is JavaScript. To switch MySQL Shell to Python mode, use the \texttt{\py} command.

\texttt{mysql-js>} \texttt{\py}

Switching to Python mode...

\texttt{mysql-py>}

MySQL Shell supports input-line editing as follows:

- \texttt{left-arrow} and \texttt{right-arrow} keys move horizontally within the current input line.
- \texttt{up-arrow} and \texttt{down-arrow} keys move up and down through the set of previously entered lines.
- \texttt{Backspace} deletes the character before the cursor and typing new characters enters them at the cursor position.
- \texttt{Enter} sends the current input line to the server.

\textbf{Get Help for MySQL Shell}

Type \texttt{mysqlsh --help} at the prompt of your command interpreter for a list of command-line options.

\texttt{mysqlsh --help}

Type \texttt{\help} at the MySQL Shell prompt for a list of available commands and their descriptions.

\texttt{mysql-py> \help}

Type \texttt{\help} followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the \texttt{\connect} command, issue:

\texttt{mysql-py> \help \connect}
Quit MySQL Shell

To quit MySQL Shell, issue the following command:

```
mysql-py> \quit
```

Related Information

- See Interactive Code Execution for an explanation of how interactive code execution works in MySQL Shell.
- See Getting Started with MySQL Shell to learn about session and connection alternatives.

22.4.2 Download and Import world_x Database

As part of this quick-start guide, an example schema is provided which is referred to as the `world_x` schema. Many of the examples demonstrate Document Store functionality using this schema. Start your MySQL server so that you can load the `world_x` schema, then follow these steps:

1. Download `world_x-db.zip`.
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Import the `world_x.sql` file to your server. You can either:
   - Start MySQL Shell in SQL mode and import the file by issuing:
     ```
     mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
     Enter password: ****
     ```
   - Set MySQL Shell to SQL mode while it is running and source the schema file by issuing:
     ```
     \sql
     Switching to SQL mode... Commands end with ;
     \source /tmp/world_x-db/world_x.sql
     ```
     Replace `/tmp/` with the path to the `world_x.sql` file on your system. Enter your password if prompted. A non-root account can be used as long as the account has privileges to create new schemas.

The world_x Schema

The `world_x` example schema contains the following JSON collection and relational tables:

- **Collection**
  - `countryinfo`: Information about countries in the world.

- **Tables**
  - `country`: Minimal information about countries of the world.
  - `city`: Information about some of the cities in those countries.
  - `countrylanguage`: Languages spoken in each country.

Related Information

- MySQL Shell Sessions explains session types.

22.4.3 Documents and Collections
When you are using MySQL as a Document Store, collections are containers within a schema that you can create, list, and drop. Collections contain JSON documents that you can add, find, update, and remove.

The examples in this section use the `countryinfo` collection in the `world_x` schema. For instructions on setting up the `world_x` schema, see Section 22.4.2, "Download and Import world_x Database".

**Documents**

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for Python:

  ```json
  {"field1": "value", "field2": 10, "field3": null}
  ```

  An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for Python:

  ```json
  ["Name": "Aruba", "Code": "ABW"], ["Name": "Angola", "Code": "AGO"]
  ```

MySQL supports the following Python value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- None
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

**Collections**

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects as opposed to a relational schema, used to enforce structure and constraints over data. A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

<table>
<thead>
<tr>
<th><strong>Object form</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db</code></td>
<td><code>db</code> is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the <code>db</code> variable.</td>
</tr>
<tr>
<td><code>db.get_collections()</code></td>
<td><code>db.get_collections()</code> returns a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.</td>
</tr>
</tbody>
</table>
Basic operations scoped by collections include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.add()</code></td>
<td>The <code>add()</code> method inserts one document or a list of documents into the named collection.</td>
</tr>
<tr>
<td><code>db.name.find()</code></td>
<td>The <code>find()</code> method returns some or all documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.modify()</code></td>
<td>The <code>modify()</code> method updates documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.remove()</code></td>
<td>The <code>remove()</code> method deletes one document or a list of documents from the named collection.</td>
</tr>
</tbody>
</table>

Related Information

- See Working with Collections for a general overview.
- CRUD EBNF Definitions provides a complete list of operations.

22.4.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```sql
mysql-py> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```sql
mysql-py> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` schema.

```sql
mysql-py> db.create_collection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` schema, use the `db` object's `get_collections()` method. Collections returned by the server you are currently connected to appear between brackets.

```sql
mysql-py> db.get_collections()
[
    <Collection:countryinfo>,
    <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a schema, use the `db` object's `drop_collection()` method. For example, to drop the `flags` collection from the current schema, issue:

```sql
```
The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a schema.

**Related Information**
- See Collection Objects for more examples.

### 22.4.3.2 Working with Collections

To work with the collections in a schema, use the `db` global object to access the current schema. In this example we are using the `world_x` schema imported previously, and the `countryinfo` collection. Therefore, the format of the operations you issue is `db.collection_name.operation`, where `collection_name` is the name of the collection which the operation is executed against. In the following examples, the operations are executed against the `countryinfo` collection.

#### Add a Document

Use the `add()` method to insert one document or a list of documents into an existing collection. Insert the following document into the `countryinfo` collection. As this is multi-line content, press `Enter` twice to insert the document.

```sql
mysql-py> db.countryinfo.add(
    {
        "GNP": 0.6,
        "IndepYear": 1967,
        "Name": "Sealand",
        "Code": "SEA",
        "demographics": {
            "LifeExpectancy": 79,
            "Population": 27,
        },
        "geography": {
            "Continent": "Europe",
            "Region": "British Islands",
            "SurfaceArea": 193,
        },
        "government": {
            "GovernmentForm": "Monarchy",
            "HeadOfState": "Michael Bates",
        }
    }
)
```

The method returns the status of the operation. You can verify the operation by searching for the document. For example:

```sql
mysql-py> db.countryinfo.find("Name = 'Sealand'")
{
    "GNP": 0.6,
    "_id": "000005e2ff4af000000000000000000f4",
    "Name": "Sealand",
    "Code": "SEA",
    "IndepYear": 1967,
    "geography": {
        "Region": "British Islands",
        "Continent": "Europe",
        "SurfaceArea": 193,
    },
    "government": {
        "GovernmentForm": "Monarchy",
        "HeadOfState": "Michael Bates",
    },
    "demographics": {
        "Population": 27,
        "LifeExpectancy": 79
    }
}
```
Note that in addition to the fields specified when the document was added, there is one more field, the _id. Each document requires an identifier field called _id. The value of the _id field must be unique among all documents in the same collection. Document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an _id value. MySQL sets an _id value if the document does not contain the _id field. For more information, see Understanding Document IDs.

Related Information

- See CollectionAddFunction for the full syntax definition.
- See Understanding Document IDs.

22.4.3.3 Find Documents

You can use the find() method to query for and return documents from a collection in a schema. MySQL Shell provides additional methods to use with the find() method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: OR ( | | ), AND (&&), XOR, IS, NOT, BETWEEN, IN, LIKE, !=, <>, >=, <, <=, |, <<, >>, +, -, *, /, ~, and %.

Find All Documents in a Collection

To return all documents in a collection, use the find() method without specifying search conditions. For example, the following operation returns all documents in the countryinfo collection.

```python
mysql-py> db.countryinfo.find()

[{
    "GNP": 828,
    "Code": "ABW",
    "Name": "Aruba",
    "IndepYear": null,
    "geography": {
        "Continent": "North America",
        "Region": "Caribbean",
        "SurfaceArea": 193
    },
    "government": {
        "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
        "HeadOfState": "Beatrix"
    },
    "demographics": {
        "LifeExpectancy": 78.4000015258789,
        "Population": 103000
    }
}, ...
]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the find() method. The syntax for expressions that form a search condition is the same as that of traditional MySQL Chapter 14, Functions and Operators. You
must enclose all expressions in quotes. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the Name field and a value we know is in a document. The following example returns a single document:

```python
mysql-py> db.countryinfo.find("Name = 'Australia'")
[{
  "GNP": 351182,
  "Code": "AUS",
  "Name": "Australia",
  "IndepYear": 1901,
  "geography": {
    "Continent": "Oceania",
    "Region": "Australia and New Zealand",
    "SurfaceArea": 7741220
  },
  "government": {
    "GovernmentForm": "Constitutional Monarchy, Federation",
    "HeadOfState": "Elisabeth II"
  }
}]
```

The following example searches for all countries that have a GNP higher than $500 billion. The countryinfo collection measures GNP in units of million.

```python
mysql-py> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case-sensitive.

```python
mysql-py> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than $30000. Search conditions can include arithmetic operators and most MySQL functions.

```python
mysql-py> db.countryinfo.find("GNP*100000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the bind() method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as country. Then use the `bind(placeholder, value)` method as follows:
Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```python
mysql-py> myFind = db.countryinfo.find("Name = :country")
mysql-py> myFind.bind('country', 'France')
{  
  "GNP": 1424285,  
  "_id": "0005de917d80000000000048",  
  "Code": "FRA",  
  "Name": "France",  
  "IndepYear": 843,  
  "geography": {  
    "Region": "Western Europe",  
    "Continent": "Europe",  
    "SurfaceArea": 551500  
  },  
  "government": {  
    "HeadOfState": "Jacques Chirac",  
    "GovernmentForm": "Republic"  
  },  
  "demographics": {  
    "Population": 59225700,  
    "LifeExpectancy": 78.80000305175781  
  }
}
1 document in set (0.0028 sec)
```
Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```sql
mysql-py> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[{
    "GNP": 8510700,
    "Name": "United States"
}]
```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```sql
mysql-py> db.countryinfo.find().fields(
        mysqlx.expr('"Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population')
    ).limit(2)
{
    "Name": "ARUBA",
    "GNPPerCapita": 8038.834951456311
}
{
    "Name": "AFGHANISTAN",
    "GNPPerCapita": 263.0281690140845
}
```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```sql
mysql-py> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)
```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the IndepYear field and then returns the first eight documents in descending order.

```sql
```
By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

**Related Information**

- The [MySQL Reference Manual](https://dev.mysql.com/doc/) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](https://dev.mysql.com/doc/) for the full syntax definition.

### 22.4.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

#### Set and Unset Document Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```
mysql-py> db.countryinfo.modify("Code = 'SEA'").set("demographics", {"LifeExpectancy": 78, "Population": 28})
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```
mysql-py> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
```

Use the `find()` method to verify the change.

```
mysql-py> db.countryinfo.find("Name = 'Sealand'")
{  
    "_id": "00005e2ff4af0000000000000000f4",  
    "Name": "Sealand",  
    "Code": "SEA",  
    "IndepYear": 1967,  
    "geography": {  
        "Region": "British Islands",  
        "Continent": "Europe",  
        "SurfaceArea": 193  
    },  
    "government": {  
        "HeadOfState": "Michael Bates",  
        "GovernmentForm": "Monarchy"  
    },  
    "demographics": {  
        "Population": 27,  
```
Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `array_append()`, `array_insert()`, or `array_delete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new `Airports` field in all documents.

```sql
mysql-py> db.countryinfo.modify("true").set("Airports", [])
```

With the `Airports` field added, the next example uses the `array_append()` method to add a new airport to one of the documents. `$$.Airports` in the following example represents the `Airports` field of the current document.

```sql
mysql-py> db.countryinfo.modify("Name = 'France'").array_append("$.Airports", "ORY")
```

Use `find()` to see the change.

```sql
mysql-py> db.countryinfo.find("Name = 'France'")
{
   "GNP": 1424285,
   "_id": "00005de917d800000000000048",
   "Code": "FRA",
   "Name": "France",
   "Airports": [
     "ORY"
   ],
   "IndepYear": 843,
   "geography": {
     "Region": "Western Europe",
     "Continent": "Europe",
     "SurfaceArea": 551500
   },
   "government": {
     "HeadOfState": "Jacques Chirac",
     "GovernmentForm": "Republic"
   },
   "demographics": {
     "Population": 59225700,
     "LifeExpectancy": 78.80000305175781
   }
}
```

To insert an element at a different position in the array, use the `array_insert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```sql
mysql-py> db.countryinfo.modify("Name = 'France'").array_insert("$.Airports[0]", "CDG")
```

To delete an element from the array, you must pass to the `array_delete()` method the index of the element to be deleted.

```sql
mysql-py> db.countryinfo.modify("Name = 'France'").array_delete("$.Airports[1]"
```

**Related Information**

- The [MySQL Reference Manual](#) provides instructions to help you search for and modify JSON values.
22.4.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a schema. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The following example passes a search condition to the `remove()` method. All documents matching the condition are removed from the `countryinfo` collection. In this example, one document matches the condition.

```python
mysql-py> db.countryinfo.remove("Code = 'SEA'")
```

Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```python
mysql-py> db.countryinfo.remove("true").limit(1)
```

Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```python
mysql-py> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying a search condition.

⚠️ **Caution**

Use care when you remove documents without specifying a search condition. This action deletes all documents from the collection.

Alternatively, use the `db.drop_collection('countryinfo')` operation to delete the `countryinfo` collection.

Related Information

- See `CollectionRemoveFunction` for the full syntax definition.
- See Section 22.4.2, “Download and Import world_x Database” for instructions to recreate the `world_x` schema.

22.4.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query performs better with an index on the Population field:

```python
mysql-py> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```
The `create_index()` method creates an index that you can define with a JSON document that specifies which fields to use. This section is a high level overview of indexing. For more information see Indexing Collections.

**Add a Nonunique Index**

To create a nonunique index, pass an index name and the index information to the `create_index()` method. Duplicate index names are prohibited.

The following example specifies an index named `popul`, defined against the `Population` field from the `demographics` object, indexed as an `Integer` numeric value. The final parameter indicates whether the field should require the `NOT NULL` constraint. If the value is `false`, the field can contain `NULL` values. The index information is a JSON document with details of one or more fields to include in the index. Each field definition must include the full document path to the field, and specify the type of the field.

```python
db.countryinfo.createIndex("popul", {fields: [{field: ".demographics.Population", type: "INTEGER"}]})
```

Here, the index is created using an integer numeric value. Further options are available, including options for use with GeoJSON data. You can also specify the type of index, which has been omitted here because the default type “index” is appropriate.

**Add a Unique Index**

To create a unique index, pass an index name, the index definition, and the index type “unique” to the `create_index()` method. This example shows a unique index created on the country name ("Name"), which is another common field in the `countryinfo` collection to index. In the index field description, "TEXT(40)" represents the number of characters to index, and "required": `True` specifies that the field is required to exist in the document.

```python
db.countryinfo.create_index("name", 
    {"fields": [{"field": ".Name", "type": "TEXT(40)", "required": True}], "unique": True})
```

**Drop an Index**

To drop an index, pass the name of the index to drop to the `drop_index()` method. For example, you can drop the “popul” index as follows:

```python
db.countryinfo.drop_index("popul")
```

**Related Information**

- See Indexing Collections for more information.
- See Defining an Index for more information on the JSON document that defines an index.
- See Collection Index Management Functions for the full syntax definition.

**22.4.4 Relational Tables**

You can also use X DevAPI to work with relational tables. In MySQL, each relational table is associated with a particular storage engine. The examples in this section use InnoDB tables in the `world_x` schema.

**Confirm the Schema**

To show the schema that is assigned to the `db` global variable, issue `db`.

```python
<Schema:world_x>
```

If the returned value is not `Schema:world_x`, set the `db` variable as follows:
Show All Tables

To display all relational tables in the `world_x` schema, use the `get_tables()` method on the `db` object.

```
mysql-py> db.get_tables()
[
    <Table:city>,
    <Table:country>,
    <Table:countrylanguage>
]
```

Basic Table Operations

Basic operations scoped by tables include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.insert()</code></td>
<td>The <code>insert()</code> method inserts one or more records into the named table.</td>
</tr>
<tr>
<td><code>db.name.select()</code></td>
<td>The <code>select()</code> method returns some or all records in the named table.</td>
</tr>
<tr>
<td><code>db.name.update()</code></td>
<td>The <code>update()</code> method updates records in the named table.</td>
</tr>
<tr>
<td><code>db.name.delete()</code></td>
<td>The <code>delete()</code> method deletes one or more records from the named table.</td>
</tr>
</tbody>
</table>

Related Information

- See [Working with Relational Tables](#) for more information.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 22.4.2, “Download and Import world_x Database”](#) for instructions on setting up the `world_x` schema sample.

22.4.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column. For example, to add a new record to the city table in the `world_x` database, insert the following record and press `Enter` twice.

```
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode").values(
```
When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

**Related Information**

- See `TableInsertFunction` for the full syntax definition.

### 22.4.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: OR (`| |`), AND (`&&`), XOR, IS, NOT, BETWEEN, IN, LIKE, !=, <>, >=, <, <=, &&, >=, <, <=, |, |, +, -, *, /, and %.

#### Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

```bash
mysql-py> db.city.select()
+------+------------+-------------+------------+-------------------------+
<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>CountryCode</th>
<th>District</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kabul</td>
<td>AFG</td>
<td>Kabol</td>
<td>{&quot;Population&quot;: 1780000}</td>
</tr>
<tr>
<td>2</td>
<td>Qandahar</td>
<td>AFG</td>
<td>Qandahar</td>
<td>{&quot;Population&quot;: 237500}</td>
</tr>
<tr>
<td>3</td>
<td>Herat</td>
<td>AFG</td>
<td>Herat</td>
<td>{&quot;Population&quot;: 186800}</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>4079</td>
<td>Rafah</td>
<td>PSE</td>
<td>Rafah</td>
<td>{&quot;Population&quot;: 92020}</td>
</tr>
</tbody>
</table>
+------+-----------+-------------+------------+-------------------------+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

#### Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```bash
mysql-py> db.city.select(["Name", "CountryCode"])
+-------------------+-------------+
| Name              | CountryCode |
| Kabul             | AFG         |
| Qandahar          | AFG         |
| Herat             | AFG         |
| Mazar-e-Sharif    | AFG         |
| Amsterdam         | NLD         |
| ...               | ...         |
| Rafah             | PSE         |
| Olympia           | USA         |
| Little Falls      | USA         |
```

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.
To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```python
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zaanstad</td>
<td>NLD</td>
</tr>
<tr>
<td>Zoetermeer</td>
<td>NLD</td>
</tr>
<tr>
<td>Zwolle</td>
<td>NLD</td>
</tr>
<tr>
<td>Zenica</td>
<td>BIH</td>
</tr>
<tr>
<td>Zagazig</td>
<td>EGY</td>
</tr>
<tr>
<td>Zaragoza</td>
<td>ESP</td>
</tr>
<tr>
<td>Zamboanga</td>
<td>PHL</td>
</tr>
<tr>
<td>Zahedan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zanjan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zabol</td>
<td>IRN</td>
</tr>
<tr>
<td>Zama</td>
<td>JPN</td>
</tr>
<tr>
<td>Zhezqazghan</td>
<td>KAZ</td>
</tr>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>

59 rows in set (0.00 sec)

You can separate a value from the search condition by using the `bind()` method. For example, instead of using "Name = 'Z%'" as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```python
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like :name").bind("name", "Z%")
```

### Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

**Project Results**

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```python
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%' and CountryCode = 'CHN'")
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiang</td>
<td>CHN</td>
</tr>
<tr>
<td>Zigong</td>
<td>CHN</td>
</tr>
<tr>
<td>Zaozhuang</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zhangjiagang</td>
<td>CHN</td>
</tr>
</tbody>
</table>

3745
To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of **AND** and **OR** operators.

```sql
db.city.select(["Name", "CountryCode"]).where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')")
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>

**Limit, Order, and Offset Results**

You can apply the `limit()`, `order_by()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```sql
db.country.select(["Code", "Name"]).limit(5)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABW</td>
<td>Aruba</td>
</tr>
<tr>
<td>AFG</td>
<td>Afghanistan</td>
</tr>
<tr>
<td>AGO</td>
<td>Angola</td>
</tr>
<tr>
<td>AIA</td>
<td>Anguilla</td>
</tr>
<tr>
<td>ALB</td>
<td>Albania</td>
</tr>
</tbody>
</table>

5 rows in set (0.00 sec)

To specify an order for the results, append the `order_by()` method to the `select()` method. Pass to the `order_by()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order.

```sql
db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZWE</td>
<td>Zimbabwe</td>
</tr>
<tr>
<td>ZMB</td>
<td>Zambia</td>
</tr>
<tr>
<td>YUG</td>
<td>Yugoslavia</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```sql
db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3).offset(1)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZMB</td>
<td>Zambia</td>
</tr>
<tr>
<td>YUG</td>
<td>Yugoslavia</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)
22.4.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```
mysql-py> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
```

Use the `select()` method to verify the change.

```
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
```

22.4.4.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition are deleted from the city table. In this example, one record matches the condition.

```
mysql-py> db.city.delete().where("Name = 'Olympia'")
```

Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```
mysql-py> db.city.delete().limit(1)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

```
Caution
Use care when you delete records without specifying a search condition; doing so deletes all records from the table.
```
Drop a Table

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the `citytest` table from the `world_x` database, issue:

```
mysql-py> db.drop_collection("citytest")
```

Related Information

- See `TableDeleteFunction` for the full syntax definition.
- See Section 22.4.2, “Download and Import `world_x Database`” for instructions to recreate the `world_x` database.

22.4.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native JSON data type.

Examples in this section use the `city` table in the `world_x` schema.

city Table Description

The `city` table has five columns (or fields).

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>int(11)</td>
<td>NO</td>
<td>PRI</td>
<td>null</td>
<td>auto_increment</td>
</tr>
<tr>
<td>Name</td>
<td>char(35)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CountryCode</td>
<td>char(3)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>District</td>
<td>char(20)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Info</td>
<td>json</td>
<td>YES</td>
<td></td>
<td>null</td>
<td></td>
</tr>
</tbody>
</table>

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the `Info` column.

```
mysql-py> db.city.insert().values(None, "San Francisco", "USA", "California", '{"Population":830000}')
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
```

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>CountryCode</th>
<th>District</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>3793</td>
<td>New York</td>
<td>USA</td>
<td>New York</td>
<td>{&quot;Population&quot;:8008278}</td>
</tr>
<tr>
<td>3794</td>
<td>Los Angeles</td>
<td>USA</td>
<td>California,&quot;Population&quot;:3694820</td>
<td></td>
</tr>
<tr>
<td>3795</td>
<td>Chicago</td>
<td>USA</td>
<td>Illinois</td>
<td>{&quot;Population&quot;:2896016}</td>
</tr>
<tr>
<td>3796</td>
<td>Houston</td>
<td>USA</td>
<td>Texas</td>
<td>{&quot;Population&quot;:1953631}</td>
</tr>
<tr>
<td>3797</td>
<td>Philadelphia</td>
<td>USA</td>
<td>Pennsylvania,&quot;Population&quot;:1517550</td>
<td></td>
</tr>
<tr>
<td>3798</td>
<td>Phoenix</td>
<td>USA</td>
<td>Arizona</td>
<td>{&quot;Population&quot;:1321045}</td>
</tr>
<tr>
<td>3799</td>
<td>San Diego</td>
<td>USA</td>
<td>California,&quot;Population&quot;:1223400</td>
<td></td>
</tr>
<tr>
<td>3800</td>
<td>Dallas</td>
<td>USA</td>
<td>Texas</td>
<td>{&quot;Population&quot;:1188580}</td>
</tr>
<tr>
<td>3801</td>
<td>San Antonio</td>
<td>USA</td>
<td>Texas</td>
<td>{&quot;Population&quot;:1144646}</td>
</tr>
</tbody>
</table>
This section explains how to use, configure and monitor X Plugin.

### 22.5.1 Checking X Plugin Installation

X Plugin is enabled by default in MySQL 8, therefore installing or upgrading to MySQL 8 makes the plugin available. You can verify X Plugin is installed on an instance of MySQL server by using the `SHOW plugins` statement to view the plugins list.

To use MySQL Shell to verify X Plugin is installed, issue:

```bash
$> mysqlsh -u user --sqlc -P 3306 -e "SHOW plugins"
```

To use MySQL Client to verify X Plugin is installed, issue:

```bash
$> mysql -u user -p -e "SHOW plugins"
```

An example result if X Plugin is installed is highlighted here:

<table>
<thead>
<tr>
<th>Name</th>
<th>Status</th>
<th>Type</th>
<th>Library</th>
<th>License</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>mysqlx</td>
<td>ACTIVE</td>
<td>DAEMON</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td></td>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 22.5.2 Disabling X Plugin

The X Plugin can be disabled at startup by either setting `mysqlx=0` in your MySQL configuration file, or by passing in either `--mysqlx=0` or `--skip-mysqlx` when starting the MySQL server.

Alternatively, use the `--WITH_MYSQLX=OFF` CMake option to compile MySQL Server without X Plugin.

### 22.5.3 Using Encrypted Connections with X Plugin

This section explains how to configure X Plugin to use encrypted connections. For more background information, see Section 8.3, “Using Encrypted Connections”.

To enable configuring support for encrypted connections, X Plugin has `mysqlx_ssl_XXX` system variables, which can have different values from the `ssl_XXX` system variables used with MySQL Server. For example, X Plugin can have SSL key, certificate, and certificate authority files that differ from those used for MySQL Server. These variables are described at Section 22.5.6.2, “X Plugin Options and System Variables”. Similarly, X Plugin has its own `Mysqlx_ssl_XXX` status variables that correspond to the MySQL Server encrypted-connection `Ssl_XXX` status variables. See Section 22.5.6.3, “X Plugin Status Variables”.

At initialization, X Plugin determines its TLS context for encrypted connections as follows:
Using X Plugin with the Caching SHA-2 Authentication Plugin

- If all \texttt{mysqlx_ssl_}xxx system variables have their default values, X Plugin uses the same TLS context as the MySQL Server main connection interface, which is determined by the values of the \texttt{ssl_}xxx system variables.

- If any \texttt{mysqlx_ssl_}xxx variable has a nondefault value, X Plugin uses the TLS context defined by the values of its own system variables. (This is the case if any \texttt{mysqlx_ssl_}xxx system variable is set to a value different from its default.)

This means that, on a server with X Plugin enabled, you can choose to have MySQL Protocol and X Protocol connections share the same encryption configuration by setting only the \texttt{ssl_}xxx variables, or have separate encryption configurations for MySQL Protocol and X Protocol connections by configuring the \texttt{ssl_}xxx and \texttt{mysqlx_ssl_}xxx variables separately.

To have MySQL Protocol and X Protocol connections use the same encryption configuration, set only the \texttt{ssl_}xxx system variables in \texttt{my.cnf}:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

To configure encryption separately for MySQL Protocol and X Protocol connections, set both the \texttt{ssl_}xxx and \texttt{mysqlx_ssl_}xxx system variables in \texttt{my.cnf}:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem

mysqlx_ssl_ca=ca2.pem
mysqlx_ssl_cert=server-cert2.pem
mysqlx_ssl_key=server-key2.pem
```

For general information about configuring connection-encryption support, see Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”. That discussion is written for MySQL Server, but the parameter names are similar for X Plugin. (The X Plugin \texttt{mysqlx_ssl_}xxx system variable names correspond to the MySQL Server \texttt{ssl_}xxx system variable names.)

The \texttt{tls_version} system variable that determines the permitted TLS versions for MySQL Protocol connections also applies to X Protocol connections. The permitted TLS versions for both types of connections are therefore the same.

Encryption per connection is optional, but a specific user can be required to use encryption for X Protocol and MySQL Protocol connections by including an appropriate \texttt{REQUIRE} clause in the \texttt{CREATE USER} statement that creates the user. For details, see Section 15.7.1.3, “CREATE USER Statement”. Alternatively, to require all users to use encryption for X Protocol and MySQL Protocol connections, enable the \texttt{require_secure_transport} system variable. For additional information, see Configuring Encrypted Connections as Mandatory.

### 22.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin

X Plugin supports MySQL user accounts created with the \texttt{caching_sha2_password} authentication plugin. For more information on this plugin, see Section 8.4.1.2, “Caching SHA-2 Pluggable Authentication”. You can use X Plugin to authenticate against such accounts using non-SSL connections with \texttt{SHA256_MEMORY} authentication and SSL connections with \texttt{PLAIN} authentication.

Although the \texttt{caching_sha2_password} authentication plugin holds an authentication cache, this cache is not shared with X Plugin, so X Plugin uses its own authentication cache for \texttt{SHA256_MEMORY} authentication. The X Plugin authentication cache stores hashes of user account passwords, and cannot be accessed using SQL. If a user account is modified or removed, the relevant entries are removed from the cache. The X Plugin authentication cache is maintained by the \texttt{mysqlx_cache_cleaner} plugin, which is enabled by default, and has no related system variables or status variables.
Before you can use non-SSL X Protocol connections to authenticate an account that uses the caching_sha2_password authentication plugin, the account must have authenticated at least once over an X Protocol connection with SSL, to supply the password to the X Plugin authentication cache. Once this initial authentication over SSL has succeeded, non-SSL X Protocol connections can be used.

It is possible to disable the mysqlx_cache_cleaner plugin by starting the MySQL server with the option --mysqlx_cache_cleaner=0. If you do this, the X Plugin authentication cache is disabled, and therefore SSL must always be used for X Protocol connections when authenticating with SHA256_MEMORY authentication.

### 22.5.5 Connection Compression with X Plugin

X Plugin supports compression of messages sent over X Protocol connections. Connections can be compressed if the server and the client agree on a mutually supported compression algorithm. Enabling compression reduces the number of bytes sent over the network, but adds to the server and client an additional CPU cost for compression and decompression operations. The benefits of compression therefore occur primarily when there is low network bandwidth, network transfer time dominates the cost of compression and decompression operations, and result sets are large.

**Note**

Different MySQL clients implement support for connection compression differently; consult your client documentation for details. For example, for classic MySQL protocol connections, see Section 6.2.8, “Connection Compression Control”.

- Configuring Connection Compression for X Plugin
- Compressed Connection Characteristics for X Plugin
- Monitoring Connection Compression for X Plugin

#### Configuring Connection Compression for X Plugin

By default, X Plugin supports the zstd, LZ4, and Deflate compression algorithms. Compression with the Deflate algorithm is carried out using the zlib software library, so the deflate_stream compression algorithm setting for X Protocol connections is equivalent to the zlib setting for classic MySQL protocol connections.

On the server side, you can disallow any of the compression algorithms by setting the mysqlx_compression_algorithms system variable to include only those permitted. The algorithm names zstd_stream, lz4_message, and deflate_stream can be specified in any combination, and the order and lettercase are not important. If the system variable value is the empty string, no compression algorithms are permitted and connections are uncompressed.

The following table compares the characteristics of the different compression algorithms and shows their assigned priorities. By default, the server chooses the highest-priority algorithm permitted in common by the server and the client; clients may change the priorities as described later. The short form alias for the algorithms can be used by clients when specifying them.

**Table 22.1 X Protocol Compression Algorithm Characteristics**

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Alias</th>
<th>Compression Ratio</th>
<th>Throughput</th>
<th>CPU Cost</th>
<th>Default Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>zstd_stream</td>
<td>zstd</td>
<td>High</td>
<td>High</td>
<td>Medium</td>
<td>First</td>
</tr>
<tr>
<td>lz4_message</td>
<td>lz4</td>
<td>Low</td>
<td>High</td>
<td>Lowest</td>
<td>Second</td>
</tr>
<tr>
<td>deflate_stream</td>
<td>deflate</td>
<td>High</td>
<td>Low</td>
<td>Highest</td>
<td>Third</td>
</tr>
</tbody>
</table>

The X Protocol set of permitted compression algorithms (whether user-specified or default) is independent of the set of compression algorithms permitted by MySQL Server for classic MySQL
Connection Compression with X Plugin

protocol connections, which is specified by the `protocol_compression_algorithms` server system variable. If you do not specify the `mysqlx_compression_algorithms` system variable, X Plugin does not fall back to using compression settings for classic MySQL protocol connections. Instead, its default is to permit all algorithms shown in Table 22.1, “X Protocol Compression Algorithm Characteristics”. This is unlike the situation for the TLS context, where MySQL Server settings are used if the X Plugin system variables are not set, as described in Section 22.5.3, “Using Encrypted Connections with X Plugin”. For information about compression for classic MySQL protocol connections, see Section 6.2.8, “Connection Compression Control”.

On the client side, an X Protocol connection request can specify several parameters for compression control:

- The compression mode.
- The compression level.
- The list of permitted compression algorithms in priority order.

Note
Some clients or Connectors might not support a given compression-control feature. For example, specifying compression level for X Protocol connections is supported only by MySQL Shell, not by other MySQL clients or Connectors. See the documentation for specific products for details about supported features and how to use them.

The connection mode has these permitted values:

- **disabled**: The connection is uncompressed.
- **preferred**: The server and client negotiate to find a compression algorithm they both permit. If no common algorithm is available, the connection is uncompressed. This is the default mode if not specified explicitly.
- **required**: Compression algorithm negotiation occurs as for preferred mode, but if no common algorithm is available, the connection request terminates with an error.

In addition to agreeing on a compression algorithm for each connection, the server and client can agree on a compression level from the numeric range that applies to the agreed algorithm. As the compression level for an algorithm increases, the data compression ratio increases, which reduces the network bandwidth and transfer time needed to send the message to the client. However, the effort required for data compression also increases, taking up time and CPU and memory resources on the server. Increases in the compression effort do not have a linear relationship to increases in the compression ratio.

The client can request a specific compression level during capability negotiations with the server for an X Protocol connection.

The default compression levels used by X Plugin in MySQL 8.4 have been selected through performance testing as being a good trade-off between compression time and network transit time. These defaults are not necessarily the same as the library default for each algorithm. They apply if the client does not request a compression level for the algorithm. The default compression levels are initially set to 3 for zstd, 2 for LZ4, and 3 for Deflate. You can adjust these settings using the `mysqlx_zstd_default_compression_level`, `mysqlx_lz4_default_compression_level`, and `mysqlx_deflate_default_compression_level` system variables.

To prevent excessive resource consumption on the server, X Plugin sets a maximum compression level that the server permits for each algorithm. If a client requests a compression level that exceeds this setting, the server uses its maximum permitted compression level (compression level requests by a client are supported only by MySQL Shell). The maximum compression levels are initially set to 11 for zstd, 8 for LZ4, and 5 for Deflate. You can...
adjust these settings using the `mysqlx_zstd_max_client_compression_level`, `mysqlx_lz4_max_client_compression_level`, and `mysqlx_deflate_max_client_compression_level` system variables.

If the server and client permit more than one algorithm in common, the default priority order for choosing an algorithm during negotiation is shown in Table 22.1, “X Protocol Compression Algorithm Characteristics”. For clients that support specifying compression algorithms, the connection request can include a list of algorithms permitted by the client, specified using the algorithm name or its alias. The order of these algorithms in the list is taken as a priority order by the server. The algorithm used in this case is the first of those in the client list that is also permitted on the server side. However, the option for compression algorithms is subject to the compression mode:

- If the compression mode is `disabled`, the compression algorithms option is ignored.
- If the compression mode is `preferred` but no algorithm permitted on the client side is permitted on the server side, the connection is uncompressed.
- If the compression mode is `required` but no algorithm permitted on the client side is permitted on the server side, an error occurs.

To monitor the effects of message compression, use the X Plugin status variables described in Monitoring Connection Compression for X Plugin. You can use these status variables to calculate the benefit of message compression with your current settings, and use that information to tune your settings.

**Compressed Connection Characteristics for X Plugin**

X Protocol connection compression operates with the following behaviors and boundaries:

- The `_stream` and `_message` suffixes in algorithm names refer to two different operational modes: In stream mode, all X Protocol messages in a single connection are compressed into a continuous stream and must be decompressed in the same manner—following the order they were compressed and without skipping any messages. In message mode, each message is compressed individually and independently, and need not be decompressed in the order in which they were compressed. Also, message mode does not require all compressed messages to be decompressed.
- Compression is not applied to any messages that are sent before authentication succeeds.
- Compression is not applied to control flow messages such as `Mysqlx.Ok`, `Mysqlx.Error`, and `Mysqlx.Sql.StmtExecuteOk` messages.
- All other X Protocol messages can be compressed if the server and client agree on a mutually permitted compression algorithm during capability negotiation. If the client does not request compression at that stage, neither the client nor the server applies compression to messages.
- When messages sent over X Protocol connections are compressed, the limit specified by the `mysqlx_max_allowed_packet` system variable still applies. The network packet must be smaller than this limit after the message payload has been decompressed. If the limit is exceeded, X Plugin returns a decompression error and closes the connection.
- The following points pertain to compression level requests by clients, which is supported only by MySQL Shell:
  - Compression levels must be specified by the client as an integer. If any other type of value is supplied, the connection closes with an error.
  - If a client specifies an algorithm but not a compression level, the server uses its default compression level for the algorithm.
  - If a client requests an algorithm compression level that exceeds the server maximum permitted level, the server uses the maximum permitted level.
Monitoring Connection Compression for X Plugin

You can monitor the effects of message compression using the X Plugin status variables. When message compression is in use, the session `Mysqlx_compression_algorithm` status variable shows which compression algorithm is in use for the current X Protocol connection, and `Mysqlx_compression_level` shows the compression level that was selected.

X Plugin status variables can be used to calculate the efficiency of the compression algorithms that are selected (the data compression ratio), and the overall effect of using message compression. Use the session value of the status variables in the following calculations to see what the benefit of message compression was for a specific session with a known compression algorithm. Or use the global value of the status variables to check the overall benefit of message compression for your server across all sessions using X Protocol connections, including all the compression algorithms that have been used for those sessions, and all sessions that did not use message compression. You can then tune message compression by adjusting the permitted compression algorithms, maximum compression level, and default compression level, as described in Configuring Connection Compression for X Plugin.

When message compression is in use, the `Mysqlx_bytes_sent` status variable shows the total number of bytes sent out from the server, including compressed message payloads measured after compression, any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages. The `Mysqlx_bytes_sent_compressed_payload` status variable shows the total number of bytes sent as compressed message payloads, measured after compression, and the `Mysqlx_bytes_sent_uncompressed_frame` status variable shows the total number of bytes for those same message payloads but measured before compression. The compression ratio, which shows the efficiency of the compression algorithm, can therefore be calculated using the following expression:

\[
\frac{\text{mysqlx_bytes_sent_uncompressed_frame}}{\text{mysqlx_bytes_sent_compressed_payload}}
\]

The effectiveness of compression for X Protocol messages sent by the server can be calculated using the following expression:

\[
\frac{(\text{mysqlx_bytes_sent} - \text{mysqlx_bytes_sent_compressed_payload} + \text{mysqlx_bytes_sent_uncompressed_frame})}{\text{mysqlx_bytes_sent}}
\]

For messages received by the server from clients, the `Mysqlx_bytes_received_compressed_payload` status variable shows the total number of bytes received as compressed message payloads, measured before decompression, and the `Mysqlx_bytes_received_uncompressed_frame` status variable shows the total number of bytes for those same message payloads but measured after decompression. The `Mysqlx_bytes_received` status variable includes compressed message payloads measured before decompression, any uncompressed items in compressed messages, and any uncompressed messages.

### 22.5.6 X Plugin Options and Variables

This section describes the command options and system variables that configure X Plugin, as well as the status variables available for monitoring purposes. If configuration values specified at startup time are incorrect, X Plugin could fail to initialize properly and the server does not load it. In this case, the server could also produce error messages for other X Plugin settings because it cannot recognize them.

#### 22.5.6.1 X Plugin Option and Variable Reference

This table provides an overview of the command options, system variables, and status variables provided by X Plugin.

</tbody>
</table>

This option controls how the server loads X Plugin at startup. In MySQL 8.4, X Plugin is enabled by default, but this option may be used to control its activation state.

The option value should be one of those available for plugin-loading options, as described in Section 7.6.1, “Installing and Uninstalling Plugins”.

If X Plugin is enabled, it exposes several system variables that permit control over its operation:

- `mysqlx_bind_address`
X Plugin Options and Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-bind-address=addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_bind_address</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>*</td>
</tr>
</tbody>
</table>

The network address on which X Plugin listens for TCP/IP connections. This variable is not dynamic and can be configured only at startup. This is the X Plugin equivalent of the `bind_address` system variable; see that variable description for more information.

By default, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. If `mysqlx_bind_address` is specified, its value must satisfy these requirements:

- A single address value, which may specify a single non-wildcard IP address (either IPv4 or IPv6), or a host name, or one of the wildcard address formats that permit listening on multiple network interfaces (`*, 0.0.0.0`, or `::`).
- A list of comma-separated values. When the variable names a list of multiple values, each value must specify a single non-wildcard IP address (either IPv4 or IPv6) or a host name. Wildcard address formats (`*, 0.0.0.0`, or `::`) are not allowed in a list of values.
- The value may also include a network namespace specifier.

IP addresses can be specified as IPv4 or IPv6 addresses. For any value that is a host name, X Plugin resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, X Plugin uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

X Plugin treats different types of addresses as follows:

- If the address is `*`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections for X Plugin. This value is the default. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is `0.0.0.0`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is `::`, X Plugin accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is an IPv4-mapped address, X Plugin accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if X Plugin is bound to `::ffff:127.0.0.1`, a client such as MySQL Shell can connect using `--host=127.0.0.1` or `--host::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), X Plugin accepts TCP/IP connections only for that IPv4 or IPv6 address.

These rules apply to specifying a network namespace for an address:

- A network namespace can be specified for an IP address or a host name.
- A network namespace cannot be specified for a wildcard IP address.
For a given address, the network namespace is optional. If given, it must be specified as a `/ns` suffix immediately following the address.

An address with no `/ns` suffix uses the host system global namespace. The global namespace is therefore the default.

An address with a `/ns` suffix uses the namespace named `ns`.

The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.

If the variable value specifies multiple addresses, it can include addresses in the global namespace, in named namespaces, or a mix.

For additional information about network namespaces, see Section 7.1.14, “Network Namespace Support”.

### Important

Because X Plugin is not a mandatory plugin, it does not prevent server startup if there is an error in the specified address or list of addresses (as MySQL Server does for `bind_address` errors). With X Plugin, if one of the listed addresses cannot be parsed or if X Plugin cannot bind to it, the address is skipped, an error message is logged, and X Plugin attempts to bind to each of the remaining addresses. X Plugin's `Mysqlx_address` status variable displays only those addresses from the list for which the bind succeeded. If none of the listed addresses results in a successful bind, or if a single specified address fails, X Plugin logs the error message `ER_XPLUGIN_FAILED_TO_PREPARE_IO_INTERFACES` stating that X Protocol cannot be used. `mysqlx_bind_address` is not dynamic, so to fix any issues you must stop the server, correct the system variable value, and restart the server.

### mysqlx_compression_algorithms

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-compression-algorithms=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_compression_algorithms</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>deflate_stream,lz4_message,zstd_stream</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>deflate_stream</code></td>
</tr>
<tr>
<td></td>
<td><code>lz4_message</code></td>
</tr>
<tr>
<td></td>
<td><code>zstd_stream</code></td>
</tr>
</tbody>
</table>

The compression algorithms that are permitted for use on X Protocol connections. By default, the Deflate, LZ4, and zstd algorithms are all permitted. To disallow any of the algorithms, set `mysqlx_compression_algorithms` to include only the ones you permit. The algorithm names `deflate_stream`, `lz4_message`, and `zstd_stream` can be specified in any combination, and the order and case are not important. If you set the system variable to the empty string, no compression algorithms are permitted and only uncompressed connections are used. Use the algorithm-specific system variables to adjust the default and maximum compression level for each permitted algorithm.
For more details, and information on how connection compression for X Protocol relates to the equivalent settings for MySQL Server, see Section 22.5.5, “Connection Compression with X Plugin”.

- **mysqlx_connect_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-connect-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_connect_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000000</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

  The number of seconds X Plugin waits for the first packet to be received from newly connected clients. This is the X Plugin equivalent of `connect_timeout`; see that variable description for more information.

- **mysqlx_deflate_default_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx_deflate_default_compression_level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_deflate_default_compression_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>9</td>
</tr>
</tbody>
</table>

  The default compression level that the server uses for the Deflate algorithm on X Protocol connections. Specify the level as an integer from 1 (the lowest compression effort) to 9 (the highest effort). This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 3 as the default. For more information, see Section 22.5.5, “Connection Compression with X Plugin”.

- **mysqlx_deflate_max_client_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx_deflate_max_client_compression_level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_deflate_max_client_compression_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
</tbody>
</table>
The maximum compression level that the server permits for the Deflate algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 5.

- **mysqlx_document_id_unique_prefix**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-document-id-unique-prefix=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_document_id_unique_prefix</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Sets the first 4 bytes of document IDs generated by the server when documents are added to a collection. By setting this variable to a unique value per instance, you can ensure document IDs are unique across instances. See Understanding Document IDs.

- **mysqlx_enable_hello_notice**

  | Command-Line Format          | `--mysqlx-enable-hello-notice[={OFF|ON}]` |
  |-----------------------------|------------------------------------------|
  | System Variable             | `mysqlx_enable_hello_notice`              |
  | Scope                       | Global                                   |
  | Dynamic                     | Yes                                      |
  | `SET_VAR` Hint Applies      | No                                       |
  | Type                        | Boolean                                  |
  | Default Value               | ON                                       |

Controls messages sent to classic MySQL protocol clients that try to connect over X Protocol. When enabled, clients which do not support X Protocol that attempt to connect to the server X Protocol port receive an error explaining they are using the wrong protocol.

- **mysqlx_idle_worker_thread_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-idle-worker-thread-timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_idle_worker_thread_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
### X Plugin Options and Variables

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>3600</td>
<td>seconds</td>
</tr>
<tr>
<td>Unit</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The number of seconds after which idle worker threads are terminated.

- **mysqlx_interactive_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-interactive-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_interactive_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>28800</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

The default value of the mysqlx_wait_timeout session variable for interactive clients. (The number of seconds to wait for interactive clients to timeout.)

- **mysqlx_lz4_default_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx_lz4_default_compression_level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_lz4_default_compression_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16</td>
</tr>
</tbody>
</table>

The default compression level that the server uses for the LZ4 algorithm on X Protocol connections. Specify the level as an integer from 0 (the lowest compression effort) to 16 (the highest effort). This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 2 as the default. For more information, see Section 22.5.5, "Connection Compression with X Plugin".

- **mysqlx_lz4_max_client_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx_lz4_max_client_compression_level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_lz4_max_client_compression_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
The maximum compression level that the server permits for the LZ4 algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 8.

* `mysqlx_max_allowed_packet`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-max-allowed-packet=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_max_allowed_packet</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>67108864</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>512</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

The maximum size of network packets that can be received by X Plugin. This limit also applies when compression is used for the connection, so the network packet must be smaller than this size after the message has been decompressed. This is the X Plugin equivalent of `max_allowed_packet`; see that variable description for more information.

* `mysqlx_max_connections`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-max-connections=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_max_connections</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The maximum number of concurrent client connections X Plugin can accept. This is the X Plugin equivalent of `max_connections`; see that variable description for more information.

For modifications to this variable, if the new value is smaller than the current number of connections, the new limit is taken into account only for new connections.

* `mysqlx_min_worker_threads`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-min-worker-threads=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_min_worker_threads</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Dynamic Options and Variables

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
<td></td>
</tr>
</tbody>
</table>

The minimum number of worker threads used by X Plugin for handling client requests.

- **mysqlx_port**

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--mysqlx-port=port_num</td>
<td></td>
</tr>
<tr>
<td>System Variable</td>
<td>mysqlx_port</td>
<td></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
<td></td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>33060</td>
<td></td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
<td></td>
</tr>
</tbody>
</table>

The network port on which X Plugin listens for TCP/IP connections. This is the X Plugin equivalent of `port`; see that variable description for more information.

- **mysqlx_port_open_timeout**

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--mysqlx-port-open-timeout=#</td>
<td></td>
</tr>
<tr>
<td>System Variable</td>
<td>mysqlx_port_open_timeout</td>
<td></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
<td></td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td>120</td>
<td></td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
<td></td>
</tr>
</tbody>
</table>

The number of seconds X Plugin waits for a TCP/IP port to become free.

- **mysqlx_read_timeout**

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--mysqlx-read-timeout=#</td>
<td></td>
</tr>
<tr>
<td>System Variable</td>
<td>mysqlx_read_timeout</td>
<td></td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
<td></td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
<td></td>
</tr>
</tbody>
</table>
X Plugin Options and Variables

Minimum Value 1
Maximum Value 2147483
Unit seconds

The number of seconds that X Plugin waits for blocking read operations to complete. After this time, if the read operation is not successful, X Plugin closes the connection and returns a warning notice with the error code ER_IO_READ_ERROR to the client application.

**mysqlx_socket**

Command-Line Format --mysqlx-socket=file_name
System Variable mysqlx_socket
Scope Global
Dynamic No
SET_VAR Hint Applies No
Type String
Default Value /tmp/mysqlx.sock

The path to a Unix socket file which X Plugin uses for connections. This setting is only used by MySQL Server when running on Unix operating systems. Clients can use this socket to connect to MySQL Server using X Plugin.

The default mysqlx_socket path and file name is based on the default path and file name for the main socket file for MySQL Server, with the addition of an `x` appended to the file name. The default path and file name for the main socket file is `/tmp/mysql.sock`, therefore the default path and file name for the X Plugin socket file is `/tmp/mysqlx.sock`.

If you specify an alternative path and file name for the main socket file at server startup using the `socket` system variable, this does not affect the default for the X Plugin socket file. In this situation, if you want to store both sockets at a single path, you must set the mysqlx_socket system variable as well. For example in a configuration file:

```
socket=/home/sockets/mysqld/mysql.sock
mysqlx_socket=/home/sockets/xplugin/xplugin.sock
```

If you change the default path and file name for the main socket file at compile time using the MYSQL_UNIX_ADDR compile option, this does affect the default for the X Plugin socket file, which is formed by appending an `x` to the MYSQL_UNIX_ADDR file name. If you want to set a different default for the X Plugin socket file at compile time, use the MYSQL_UNIX_ADDR compile option.

The MYSQL_UNIX_PORT environment variable can also be used to set a default for the X Plugin socket file at server startup (see Section 6.9, "Environment Variables"). If you set this environment variable, it overrides the compiled MYSQL_UNIX_ADDR value, but is overridden by the mysqlx_socket value.

**mysqlx_ssl_ca**

Command-Line Format --mysqlx-ssl-ca=file_name
System Variable mysqlx_ssl_ca
Scope Global
Dynamic No
SET_VAR Hint Applies No
Type File name
The `mysqlx_ssl_ca` system variable is like `ssl_ca`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 22.5.3, “Using Encrypted Connections with X Plugin”.

**mysqlx_ssl_capath**

**Command-Line Format**

```
--mysqlx-ssl-capath=dir_name
```

**System Variable**

`mysqlx_ssl_capath`

**Scope**

Global

**Dynamic**

No

**SET_VAR Hint Applies**

No

**Type**

Directory name

**Default Value**

NULL

The `mysqlx_ssl_capath` system variable is like `ssl_capath`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 22.5.3, “Using Encrypted Connections with X Plugin”.

**mysqlx_ssl_cert**

**Command-Line Format**

```
--mysqlx-ssl-cert=file_name
```

**System Variable**

`mysqlx_ssl_cert`

**Scope**

Global

**Dynamic**

No

**SET_VAR Hint Applies**

No

**Type**

File name

**Default Value**

NULL

The `mysqlx_ssl_cert` system variable is like `ssl_cert`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 22.5.3, “Using Encrypted Connections with X Plugin”.

**mysqlx_ssl_cipher**

**Command-Line Format**

```
--mysqlx-ssl-cipher=name
```

**System Variable**

`mysqlx_ssl_cipher`

**Scope**

Global

**Dynamic**

No

**SET_VAR Hint Applies**

No

**Type**

String

**Default Value**

NULL

The `mysqlx_ssl_cipher` system variable is like `ssl_cipher`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 22.5.3, “Using Encrypted Connections with X Plugin”.

**mysqlx_ssl_crl**

**Command-Line Format**

```
--mysqlx-ssl-crl=file_name
```

The `mysqlx_ssl_crl` system variable is like `ssl_crl`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 22.5.3, “Using Encrypted Connections with X Plugin”.

### X Plugin Options and Variables

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>mysqlx_write_timeout</strong></td>
<td>The number of seconds that X Plugin waits for blocking write operations to complete. After this time, if the write operation is not successful, X Plugin closes the connection.</td>
</tr>
<tr>
<td><strong>mysqlx_zstd_default_compression_level</strong></td>
<td>The default compression level that the server uses for the zstd algorithm on X Protocol connections. For versions of the zstd library from 1.4.0, you can set positive values from 1 to 22 (the highest compression effort), or negative values which represent progressively lower effort. A value of 0 is converted to a value of 1. For earlier versions of the zstd library, you can only specify the value 3. This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 3 as the default. For more information, see Section 22.5.5, “Connection Compression with X Plugin”.</td>
</tr>
<tr>
<td><strong>mysqlx_zstd_max_client_compression_level</strong></td>
<td>The maximum compression level that the client can request during capability negotiation. This value is used to set the server's compression level if the client requests compression. For more information, see Section 22.5.5, “Connection Compression with X Plugin”.</td>
</tr>
</tbody>
</table>
The maximum compression level that the server permits for the zstd algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 11.

### 22.5.6.3 X Plugin Status Variables

The X Plugin status variables have the following meanings.

- **Mysqlx_aborted_clients**
  
The number of clients that were disconnected because of an input or output error.

- **Mysqlx_address**
  
The network address or addresses for which X Plugin accepts TCP/IP connections. If multiple addresses were specified using the `mysqlx_bind_address` system variable, `Mysqlx_address` displays only those addresses for which the bind succeeded. If the bind has failed for every network address specified by `mysqlx_bind_address`, or if the `skip_networking` option has been used, the value of `Mysqlx_address` is `UNDEFINED`. If X Plugin startup is not yet complete, the value of `Mysqlx_address` is empty.

- **Mysqlx_bytes_received**
  
The total number of bytes received through the network. If compression is used for the connection, this figure comprises compressed message payloads measured before decompression (`Mysqlx_bytes_received_compressed_payload`), any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages.

- **Mysqlx_bytes_received_compressed_payload**
  
The number of bytes received as compressed message payloads, measured before decompression.

- **Mysqlx_bytes_received_uncompressed_frame**
  
The number of bytes received as compressed message payloads, measured after decompression.

- **Mysqlx_bytes_sent**
  
The total number of bytes sent through the network. If compression is used for the connection, this figure comprises compressed message payloads measured after compression (`Mysqlx_bytes_sent_compressed_payload`), any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages.

- **Mysqlx_bytes_sent_compressed_payload**
  
The number of bytes sent as compressed message payloads, measured after compression.

- **Mysqlx_bytes_sent_uncompressed_frame**
  
The number of bytes sent as compressed message payloads, measured before compression.

- **Mysqlx_compression_algorithm**
  
3769
(Session scope) The compression algorithm in use for the X Protocol connection for this session. The permitted compression algorithms are listed by the `mysqlx_compression_algorithms` system variable.

- **Mysqlx_compression_level**
  (Session scope) The compression level in use for the X Protocol connection for this session.

- **Mysqlx_connection_accept_errors**
  The number of connections which have caused accept errors.

- **Mysqlx_connection_errors**
  The number of connections which have caused errors.

- **Mysqlx_connections_accepted**
  The number of connections which have been accepted.

- **Mysqlx_connections_closed**
  The number of connections which have been closed.

- **Mysqlx_connections_rejected**
  The number of connections which have been rejected.

- **Mysqlx_crud_create_view**
  The number of create view requests received.

- **Mysqlx_crud_delete**
  The number of delete requests received.

- **Mysqlx_crud_drop_view**
  The number of drop view requests received.

- **Mysqlx_crud_find**
  The number of find requests received.

- **Mysqlx_crud_insert**
  The number of insert requests received.

- **Mysqlx_crud_modify_view**
  The number of modify view requests received.

- **Mysqlx_crud_update**
  The number of update requests received.

- **Mysqlx_cursor_close**
  The number of cursor-close messages received.

- **Mysqlx_cursor_fetch**
  The number of cursor-fetch messages received.
• **Mysqlx_cursor_open**
  The number of cursor-open messages received

• **Mysqlx_errors_sent**
  The number of errors sent to clients.

• **Mysqlx_errors_unknown_message_type**
  The number of unknown message types that have been received.

• **Mysqlx_expect_close**
  The number of expectation blocks closed.

• **Mysqlx_expect_open**
  The number of expectation blocks opened.

• **Mysqlx_init_error**
  The number of errors during initialisation.

• **Mysqlx_messages_sent**
  The total number of messages of all types sent to clients.

• **Mysqlx_notice_global_sent**
  The number of global notifications sent to clients.

• **Mysqlx_notice_other_sent**
  The number of other types of notices sent back to clients.

• **Mysqlx_notice_warning_sent**
  The number of warning notices sent back to clients.

• **Mysqlx_notified_by_group_replication**
  Number of Group Replication notifications sent to clients.

• **Mysqlx_port**
  The TCP port which X Plugin is listening to. If a network bind has failed, or if the skip_networking system variable is enabled, the value shows **UNDEFINED**.

• **Mysqlx_prep_deallocate**
  The number of prepared-statement-deallocate messages received

• **Mysqlx_prep_execute**
  The number of prepared-statement-execute messages received

• **Mysqlx_prep_prepare**
  The number of prepared-statement messages received

• **Mysqlx_rows_sent**
  The number of rows sent back to clients.
X Plugin Options and Variables

- **Mysqlx_sessions**
  The number of sessions that have been opened.

- **Mysqlx_sessions_accepted**
  The number of session attempts which have been accepted.

- **Mysqlx_sessions_closed**
  The number of sessions that have been closed.

- **Mysqlx_sessions_fatal_error**
  The number of sessions that have closed with a fatal error.

- **Mysqlx_sessions_killed**
  The number of sessions which have been killed.

- **Mysqlx_sessions_rejected**
  The number of session attempts which have been rejected.

- **Mysqlx_socket**
  The Unix socket which X Plugin is listening to.

- **Mysqlx_ssl_accept_renegotiates**
  The number of negotiations needed to establish the connection.

- **Mysqlx_ssl_accepts**
  The number of accepted SSL connections.

- **Mysqlx_ssl_active**
  If SSL is active.

- **Mysqlx_ssl_cipher**
  The current SSL cipher (empty for non-SSL connections).

- **Mysqlx_ssl_cipher_list**
  A list of possible SSL ciphers (empty for non-SSL connections).

- **Mysqlx_ssl_ctx_verify_depth**
  The certificate verification depth limit currently set in ctx.

- **Mysqlx_ssl_ctx_verify_mode**
  The certificate verification mode currently set in ctx.

- **Mysqlx_ssl_finished_accepts**
  The number of successful SSL connections to the server.

- **Mysqlx_ssl_server_not_after**
  The last date for which the SSL certificate is valid.

- **Mysqlx_ssl_server_not_before**
X Plugin Options and Variables

The first date for which the SSL certificate is valid.

- **Mysqlx_ssl_verify_depth**
  The certificate verification depth for SSL connections.

- **Mysqlx_ssl_verify_mode**
  The certificate verification mode for SSL connections.

- **Mysqlx_ssl_version**
  The name of the protocol used for SSL connections.

- **Mysqlx_stmt_create_collection**
  The number of create collection statements received.

- **Mysqlx_stmt_create_collection_index**
  The number of create collection index statements received.

- **Mysqlx_stmt_disable_notices**
  The number of disable notice statements received.

- **Mysqlx_stmt_drop_collection**
  The number of drop collection statements received.

- **Mysqlx_stmt_drop_collection_index**
  The number of drop collection index statements received.

- **Mysqlx_stmt_enable_notices**
  The number of enable notice statements received.

- **Mysqlx_stmt_ensure_collection**
  The number of ensure collection statements received.

- **Mysqlx_stmt_execute_mysqlx**
  The number of StmtExecute messages received with namespace set to `mysqlx`.

- **Mysqlx_stmt_execute_sql**
  The number of StmtExecute requests received for the SQL namespace.

- **Mysqlx_stmt_execute_xplugin**
  This status variable is no longer used.

- **Mysqlx_stmt_get_collection_options**
  The number of get collection object statements received.

- **Mysqlx_stmt_kill_client**
  The number of kill client statements received.

- **Mysqlx_stmt_list_clients**
The number of list client statements received.

- `Mysqlx_stmt_list_notices`
  The number of list notice statements received.

- `Mysqlx_stmt_list_objects`
  The number of list object statements received.

- `Mysqlx_stmt_modify_collection_options`
  The number of modify collection options statements received.

- `Mysqlx_stmt_ping`
  The number of ping statements received.

- `Mysqlx_worker_threads`
  The number of worker threads available.

- `Mysqlx_worker_threads_active`
  The number of worker threads currently used.

### 22.5.7 Monitoring X Plugin

For general X Plugin monitoring, use the status variables that it exposes. See Section 22.5.6.3, “X Plugin Status Variables”. For information specifically about monitoring the effects of message compression, see Monitoring Connection Compression for X Plugin.

### Monitoring SQL Generated by X Plugin

This section describes how to monitor the SQL statements which X Plugin generates when you run X DevAPI operations. When you execute a CRUD statement, it is translated into SQL and executed against the server. To be able to monitor the generated SQL, the Performance Schema tables must be enabled. The SQL is registered under the `performance_schema.events_statements_current`, `performance_schema.events_statements_history`, and `performance_schema.events_statements_history_long` tables. The following example uses the `world_x` schema, imported as part of the quickstart tutorials in this section. We use MySQL Shell in Python mode, and the `\sql` command which enables you to issue SQL statements without changing to SQL mode. This is important, because if you instead try to switch to SQL mode, the procedure shows the result of this operation rather than the X DevAPI operation. The `\sql` command is used in the same way if you are using MySQL Shell in JavaScript mode.

1. Check if the `events_statements_history` consumer is enabled. Issue:

   ```sql
   mysql-py> \sql SELECT enabled FROM performance_schema.setup_consumers WHERE NAME = 'events_statements_history'
   +---------+
   | enabled |
   +---------+
   | YES     |
   +---------+
   ```

2. Check if all instruments report data to the consumer. Issue:

   ```sql
   mysql-py> \sql SELECT NAME, ENABLED, TIMED FROM performance_schema.setup_instruments WHERE NAME LIKE 'statement/%' AND NOT (ENABLED and TIMED)
   ```

   If this statement reports at least one row, you need to enable the instruments. See Section 29.4, “Performance Schema Runtime Configuration”.

3. Get the thread ID of the current connection. Issue:
4. Execute the X DevAPI CRUD operation for which you want to see the generated SQL. For example, issue:

```sql
SELECT thread_id INTO @id FROM performance_schema.threads WHERE processlist_id=connection_id();
```

```python
mysql-py> db.CountryInfo.find("Name = :country").bind("country", "Italy")
```

You must not issue any further operations for the next step to show the correct result.

5. Show the last SQL query made by this thread ID. Issue:

```sql
SELECT THREAD_ID, MYSQL_ERRNO, SQL_TEXT FROM performance_schema.events_statements_history WHERE THREAD_ID=@id ORDER BY TIMER_START DESC LIMIT 1;
```

```
+-----------+-------------+--------------------------------------------------------------------------------------+
| THREAD_ID | MYSQL_ERRNO | SQL_TEXT                                                                             |
+-----------+-------------+--------------------------------------------------------------------------------------+
|        29 |           0 | SELECT doc FROM `world_x`.`CountryInfo` WHERE (JSON_EXTRACT(doc,'$.Name') = 'Italy') |
+-----------+-------------+--------------------------------------------------------------------------------------+
```

The result shows the SQL generated by X Plugin based on the most recent statement, in this case the X DevAPI CRUD operation from the previous step.
Chapter 23 InnoDB Cluster

This chapter introduces MySQL InnoDB Cluster, which combines MySQL technologies to enable you to deploy and administer a complete integrated high availability solution for MySQL. This content is a high-level overview of InnoDB Cluster, for full documentation, see MySQL InnoDB Cluster.

Important

InnoDB Cluster does not provide support for MySQL NDB Cluster. For more information about MySQL NDB Cluster, see Chapter 25, MySQL NDB Cluster 8.4 and Section 25.2.6, “MySQL Server Using InnoDB Compared with NDB Cluster”.

An InnoDB Cluster consists of at least three MySQL Server instances, and it provides high-availability and scaling features. InnoDB Cluster uses the following MySQL technologies:

- MySQL Shell, which is an advanced client and code editor for MySQL.
- MySQL Server, and Group Replication, which enables a set of MySQL instances to provide high-availability. InnoDB Cluster provides an alternative, easy to use programmatic way to work with Group Replication.
- MySQL Router, a lightweight middleware that provides transparent routing between your application and InnoDB Cluster.

The following diagram shows an overview of how these technologies work together:

Figure 23.1 InnoDB Cluster overview

Being built on MySQL Group Replication, provides features such as automatic membership management, fault tolerance, automatic failover, and so on. An InnoDB Cluster usually runs in a single-primary mode, with one primary instance (read-write) and multiple secondary instances (read-only). Advanced users can also take advantage of a multi-primary mode, where all instances are primaries. You can even change the topology of the cluster while InnoDB Cluster is online, to ensure the highest possible availability.
You work with InnoDB Cluster using the AdminAPI, provided as part of MySQL Shell. AdminAPI is available in JavaScript and Python, and is well suited to scripting and automation of deployments of MySQL to achieve high-availability and scalability. By using MySQL Shell's AdminAPI, you can avoid the need to configure many instances manually. Instead, AdminAPI provides an effective modern interface to sets of MySQL instances and enables you to provision, administer, and monitor your deployment from one central tool.

To get started with InnoDB Cluster you need to download and install MySQL Shell. You need some hosts with MySQL Server instances installed, and you can also install MySQL Router.

InnoDB Cluster supports MySQL Clone, which enables you to provision instances simply. In the past, to provision a new instance before it joins a set of MySQL instances you would need to somehow manually transfer the transactions to the joining instance. This could involve making file copies, manually copying them, and so on. Using InnoDB Cluster, you can simply add an instance to the cluster and it is automatically provisioned.

Similarly, InnoDB Cluster is tightly integrated with MySQL Router, and you can use AdminAPI to work with them together. MySQL Router can automatically configure itself based on an InnoDB Cluster, in a process called bootstrapping, which removes the need for you to configure routing manually. MySQL Router then transparently connects client applications to the InnoDB Cluster, providing routing and load-balancing for client connections. This integration also enables you to administer some aspects of a MySQL Router bootstrapped against an InnoDB Cluster using AdminAPI. InnoDB Cluster status information includes details about MySQL Routers bootstrapped against the cluster. Operations enable you to create MySQL Router users at the cluster level, to work with the MySQL Routers bootstrapped against the cluster, and so on.

For more information on these technologies, see the user documentation linked in the descriptions. In addition to this user documentation, there is developer documentation for all AdminAPI methods in the MySQL Shell JavaScript API Reference or MySQL Shell Python API Reference, available from Connectors and APIs.
Chapter 24 InnoDB ReplicaSet

This chapter introduces MySQL InnoDB ReplicaSet, which combines MySQL technologies to enable you to deploy and administer Chapter 19, Replication. This content is a high-level overview of InnoDB ReplicaSet, for full documentation, see MySQL InnoDB ReplicaSet.

An InnoDB ReplicaSet consists of at least two MySQL Server instances, and it provides all of the MySQL Replication features you are familiar with, such as read scale-out and data security. InnoDB ReplicaSet uses the following MySQL technologies:

- **MySQL Shell**, which is an advanced client and code editor for MySQL.
- MySQL Server, and Chapter 19, Replication, which enables a set of MySQL instances to provide availability and asynchronous read scale-out. InnoDB ReplicaSet provides an alternative, easy to use programmatic way to work with Replication.
- **MySQL Router**, a lightweight middleware that provides transparent routing between your application and InnoDB ReplicaSet.

The interface to an InnoDB ReplicaSet is similar to MySQL InnoDB Cluster, you use MySQL Shell to work with MySQL Server instances as a ReplicaSet, and MySQL Router is also tightly integrated in the same way as InnoDB Cluster.

Being based on MySQL Replication, an InnoDB ReplicaSet has a single primary, which replicates to one or more secondary instances. An InnoDB ReplicaSet does not provide all of the features which InnoDB Cluster provides, such as automatic failover, or multi-primary mode. But, it does support features such as configuring, adding, and removing instances in a similar way. You can manually switch over or fail over to a secondary instance, for example in the event of a failure. You can even adopt an existing Replication deployment and then administer it as an InnoDB ReplicaSet.

You work with InnoDB ReplicaSet using the AdminAPI, provided as part of MySQL Shell. AdminAPI is available in JavaScript and Python, and is well suited to scripting and automation of deployments of MySQL to achieve high-availability and scalability. By using MySQL Shell's AdminAPI, you can avoid the need to configure many instances manually. Instead, AdminAPI provides an effective modern interface to sets of MySQL instances and enables you to provision, administer, and monitor your deployment from one central tool.

To get started with InnoDB ReplicaSet you need to download and install MySQL Shell. You need some hosts with MySQL Server instances installed, and you can also install MySQL Router.

InnoDB ReplicaSet supports MySQL Clone, which enables you to provision instances simply. In the past, to provision a new instance before it joined a MySQL Replication deployment, you would need to somehow manually transfer the transactions to the joining instance. This could involve making file copies, manually copying them, and so on. You can simply add an instance to the replica set and it is automatically provisioned.

Similarly, InnoDB ReplicaSet is tightly integrated with MySQL Router, and you can use AdminAPI to work with them together. MySQL Router can automatically configure itself based on an InnoDB ReplicaSet, in a process called bootstrapping, which removes the need for you to configure routing manually. MySQL Router then transparently connects client applications to the InnoDB ReplicaSet, providing routing and load-balancing for client connections. This integration also enables you to administer some aspects of a MySQL Router bootstrapped against an InnoDB ReplicaSet using AdminAPI. InnoDB ReplicaSet status information includes details about MySQL Routers bootstrapped against the ReplicaSet. Operations enable you to create MySQL Router users at the ReplicaSet level, to work with the MySQL Routers bootstrapped against the ReplicaSet, and so on.

For more information on these technologies, see the user documentation linked in the descriptions. In addition to this user documentation, there is developer documentation for all AdminAPI methods in the MySQL Shell JavaScript API Reference or MySQL Shell Python API Reference, available from Connectors and APIs.

  25.5.18 ndb_print_file — Print NDB Disk Data File Contents ......................................... 4159
  25.5.19 ndb_print_frag_file — Print NDB Fragment List File Contents ............................. 4160
  25.5.20 ndb_print_schema_file — Print NDB Schema File Contents .............................. 4161
  25.5.21 ndb_print_sys_file — Print NDB System File Contents ....................................... 4161
  25.5.22 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log .................. 4161
  25.5.23 ndb_restore — Restore an NDB Cluster Backup .................................................... 4164
  25.5.24 ndb_secretsfile_reader — Obtain Key Information from an Encrypted NDB Data File 4185
  25.5.25 ndb_select_all — Print Rows from an NDB Table ............................................... 4187
  25.5.26 ndb_select_count — Print Row Counts for NDB Tables ........................................ 4192
  25.5.27 ndb_show_tables — Display List of NDB Tables ................................................... 4196

3781
This chapter provides information about MySQL NDB Cluster, a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment, as well as information specific to NDB Cluster 8.4 (NDB 8.4.0), based on version 8.4 of the NDB storage engine. See Section 25.2.4, “What is New in MySQL NDB Cluster 8.4”, for information about differences in NDB 8.4 as compared to earlier releases. See MySQL NDB Cluster 8.0 for information about NDB Cluster 8.0. Both NDB 8.0 and NDB 8.4 are intended for use in production environments. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production, although new deployments can and should use either of MySQL NDB Cluster 8.0 or 8.4.

NDB Cluster 7.4 and older release series are no longer supported or maintained.
25.1 General Information

MySQL NDB Cluster uses the MySQL server with the NDB storage engine. Support for the NDB storage engine is not included in standard MySQL Server 8.4 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster 8.4 users who build from source should use the sources provided for MySQL 8.4 and build with the options required to provide NDB support. (Locations where the sources can be obtained are listed later in this section.)

Important

MySQL NDB Cluster does not support InnoDB Cluster, which must be deployed using MySQL Server InnoDB storage engine as well as additional applications that are not included in the NDB Cluster distribution. MySQL Server 8.4 binaries cannot be used with MySQL NDB Cluster. For more information about deploying and using InnoDB Cluster, see MySQL AdminAPI. Section 25.2.6, “MySQL Server Using InnoDB Compared with NDB Cluster”, discusses differences between the NDB and InnoDB storage engines.

Supported Platforms. NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to https://www.mysql.com/support/supportedplatforms/cluster.html.

Availability. NDB Cluster binary and source packages are available for supported platforms from https://dev.mysql.com/downloads/cluster/.

Version strings used in NDB Cluster software. The version string displayed by the mysql client supplied with the MySQL NDB Cluster distribution uses this format:

```
mysql-mysql_server_version-cluster
```

mysql_server_version represents the version of the MySQL Server on which the NDB Cluster release is based. Building from source using -DWITH_NDB or the equivalent adds the -cluster suffix to the version string. (See Section 25.3.1.4, “Building NDB Cluster from Source on Linux”, and Section 25.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”.) You can see this format used in the mysql client, as shown here:

```
$> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 8.4.0-cluster Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SELECT VERSION()\G
+---------------------+
| VERSION()           |
+---------------------+
| 8.4.0-cluster       |
+---------------------+
1 row in set (0.00 sec)
```

The version string displayed by other NDB Cluster programs not normally included with the MySQL 8.4 distribution uses this format:

```
mysql-mysql_server_version ndb-ndb_engine_version
```

mysql_server_version represents the version of the MySQL Server on which the NDB Cluster release is based. For NDB Cluster 8.4, this is 8.4.n, where n is the release number. ndb_engine_version is the version of the NDB storage engine used by this release of the NDB Cluster software. For NDB 8.4, this number is the same as the MySQL Server version. You can see this format used in the output of the SHOW command in the ndb_mgm client, like this:
NDB Cluster Overview

 Compatibility with standard MySQL 8.4 releases. While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see Section 25.2.7, “Known Limitations of NDB Cluster”). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, MyISAM or InnoDB—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications. A mysqld compiled without NDB support (that is, built without -DWITH_NDB or -DWITH_NDBCLUSTER_STORAGE_ENGINE) cannot function as a drop-in replacement for a mysqld that is built with it.

NDB Cluster development source trees. NDB Cluster development trees can also be accessed from https://github.com/mysql/mysql-server.

The NDB Cluster development sources maintained at https://github.com/mysql/mysql-server are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see Section 2.8.5, “Installing MySQL Using a Development Source Tree”.

Note As with MySQL Server 8.4, NDB Cluster 8.4 releases are built using CMake.

NDB Cluster 8.4 is available as an LTS release, and is recommended for new deployments. NDB Cluster 8.0 is the previous GA release series (see MySQL NDB Cluster 8.0), still supported in production. NDB Cluster 7.6 and 7.5 are earlier GA releases still supported in production, although we recommend NDB Cluster 8.4 for new deployments intended for use in production.

NDB Cluster 7.4 and 7.3 were previous GA releases which have been discontinued; they are no longer maintained or supported.

Additional information regarding NDB Cluster can be found on the MySQL website at https://www.mysql.com/products/cluster/.

Additional Resources. More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see Section A.10, “MySQL 8.4 FAQ: NDB Cluster”.
- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through PlanetMySQL.

25.2 NDB Cluster Overview

NDB Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.
NDB Cluster Overview

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB (which stands for “Network DataBase”). In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas “MySQL NDB Cluster” refers to the combination of one or more MySQL servers with the NDB storage engine.

An NDB Cluster consists of a set of computers, known as hosts, each running one or more processes. These processes, known as nodes, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

**Figure 25.1 NDB Cluster Components**

All these programs work together to form an NDB Cluster (see Section 25.5, “NDB Cluster Programs”. When data is stored by the NDB storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

An NDB Cluster 8.4 SQL node uses the mysqld server daemon, which is the same as the mysqld supplied with MySQL Server 8.4 distributions. You should keep in mind that an instance of mysqld, regardless of version, that is not connected to an NDB Cluster cannot use the NDB storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.
Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”). Rolling restarts are also used as part of the process of adding new data nodes online (see Section 25.6.7, “Adding NDB Cluster Data Nodes Online”). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”.

Backing up and restoring NDB Cluster databases can be done using the NDB-native functionality found in the NDB Cluster management client and the ndb_restore program included in the NDB Cluster distribution. For more information, see Section 25.6.8, “Online Backup of NDB Cluster”, and Section 25.5.23, “ndb_restore — Restore an NDB Cluster Backup”. You can also use the standard MySQL functionality provided for this purpose in mysql dump and the MySQL server. See Section 6.5.4, “mysqldump — A Database Backup Program”, for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

### 25.2.1 NDB Cluster Core Concepts

**NDBCLUSTER** (also known as **NDB**) is an in-memory storage engine offering high-availability and data-persistence features.

The NDBCLUSTER storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster’s NDB storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a node.

**Note**

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a process. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term cluster host.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there are at least three nodes, one of each of these types:

- **Management node**: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. A management node is started with the command **ndb_mgmd**.

- **Data node**: This type of node stores cluster data. There are as many data nodes as there are fragment replicas, times the number of fragments (see Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”). For example, with two fragment replicas, each having two fragments, you need four data nodes. One fragment replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have two (or more) fragment replicas to provide redundancy, and thus high availability. A data node is started with the command **ndbd** (see Section 25.5.1, “ndbd — The NDB Cluster Data Node Daemon”) or **ndbmtd** (see Section 25.5.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see Section 25.6.11, “NDB Cluster Disk Data Tables”, for more information.

- **SQL node**: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the NDBCLUSTER storage engine. An SQL node is a **mysqld**...
process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of API node, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

Important
It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster’s high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, fragment replicas, and partitions in NDB Cluster, see Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

Standard MySQL clients. NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see Using Connector/J with NDB Cluster.

NDB client programs. Client programs can be written that access NDB Cluster data directly from the `NDBCluster` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the `NDB API`, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

NDB-specific Java applications can also be written for NDB Cluster using the `NDB Cluster Connector for Java`. This NDB Cluster Connector includes `ClusterJ`, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCluster`, and so does not require access to a MySQL Server. See Java and NDB Cluster, and The ClusterJ API and Data Object Model, for more information.

NDB Cluster also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the NDB storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object
model similar in many ways to that employed by ClusterJ. For more information, see MySQL NoSQL Connector for JavaScript.

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the ndb_mgm management client supplied with NDB Cluster (see Section 25.5.5, "ndb_mgm — The NDB Cluster Management Client"). Such applications can be written using the MGM API, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as mysqld server options and variables relating to NDB Cluster. See MySQL Cluster Manager 8.4.1 User Manual, for more information.

**Event logs.** NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 25.6.3, “Event Reports Generated in NDB Cluster”. Event logs are of the two types listed here:

- **Cluster log**: Keeps a record of all desired reportable events for the cluster as a whole.
- **Node log**: A separate log which is also kept for each individual node.

**Note**
Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster’s data is maintained. These are shown in the following list:

- **Local Checkpoint (LCP)**: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP usually occurs every few minutes; the precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

  NDB 8.4 supports partial LCPs, which can significantly improve performance under some conditions. See the descriptions of the EnablePartialLcp and RecoveryWork configuration parameters which enable partial LCPs and control the amount of storage they use.

- **Global Checkpoint (GCP)**: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see NDB Cluster Data Node File System Directory.

**Transporter.** We use the term transporter for the data transport mechanism employed between data nodes. MySQL NDB Cluster 8.4 supports three of these, which are listed here:

- **TCP/IP over Ethernet.** See Section 25.4.3.10, “NDB Cluster TCP/IP Connections”.
- **Direct TCP/IP.** Uses machine-to-machine connections. See Section 25.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”.

3788
Although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster.

- **Shared memory (SHM).** See Section 25.4.3.12, “NDB Cluster Shared-Memory Connections”.

Because it is ubiquitous, most users employ TCP/IP over Ethernet for NDB Cluster.

Regardless of the transporter used, NDB attempts to make sure that communication between data node processes is performed using chunks that are as large as possible since this benefits all types of data transmission.

### 25.2.2 NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

**Data node.** An ndbd or ndbmtd process, which stores one or more fragment replicas—that is, copies of the partitions (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an ndbd or ndbmtd process; where mentioned, management nodes (ndb_mgmd processes) and SQL nodes (mysqld processes) are specified as such in this discussion.

**Node group.** A node group consists of one or more nodes, and stores partitions, or sets of fragment replicas (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of fragment replicas (NoOfReplicas configuration parameter), as shown here:

\[
\text{[# of node groups]} = \frac{\text{[# of data nodes]}}{\text{NoOfReplicas}}
\]

Thus, an NDB Cluster with 4 data nodes has 4 node groups if NoOfReplicas is set to 1 in the config.ini file, 2 node groups if NoOfReplicas is set to 2, and 1 node group if NoOfReplicas is set to 4. Fragment replicas are discussed later in this section; for more information about NoOfReplicas, see Section 25.4.3.6, “Defining NDB Cluster Data Nodes”.

**Note**

All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see Section 25.6.7, “Adding NDB Cluster Data Nodes Online”, for more information.

**Partition.** This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one fragment replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:
When using data nodes running `ndbmt`, the number of LDM threads is controlled by the setting for `MaxNoOfExecutionThreads`. When using `ndbd` there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using `ndbmt` with `MaxNoOfExecutionThreads` set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of `MaxNoOfExecutionThreads` for more information.)

**NDB and user-defined partitioning.** NDB Cluster normally partitions `NDBCLUSTER` tables automatically. However, it is also possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only the `KEY` and `LINEAR KEY` partitioning schemes are supported in production with `NDB` tables.

2. The maximum number of partitions that may be defined explicitly for any `NDB` table is $8 \times \text{[number of LDM threads]} \times \text{[number of node groups]}$, the number of node groups in an NDB Cluster being determined as discussed previously in this section. When running `ndbd` for data node processes, setting the number of LDM threads has no effect (since `ThreadConfig` applies only to `ndbmt`); in such cases, this value can be treated as though it were equal to 1 for purposes of performing this calculation.

   See Section 25.5.3, “ndbmt — The NDB Cluster Data Node Daemon (Multi-Threaded)”, for more information.

   For more information relating to NDB Cluster and user-defined partitioning, see Section 25.2.7, “Known Limitations of NDB Cluster”, and Section 26.6.2, “Partitioning Limitations Relating to Storage Engines”.

**Fragment replica.** This is a copy of a cluster partition. Each node in a node group stores a fragment replica. Also sometimes known as a `partition replica`. The number of fragment replicas is equal to the number of nodes per node group.

A fragment replica belongs entirely to a single node; a node can (and usually does) store several fragment replicas.

The following diagram illustrates an NDB Cluster with four data nodes running `ndbd`, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

**Note**

Only data nodes are shown here; although a working NDB Cluster requires an `ndbd_mgmd` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.
The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a primary fragment replica (primary copy) is stored on node 1, and a backup fragment replica (backup copy of the partition) is stored on node 2.

- Partition 1 is stored on the other node group (node group 1); this partition's primary fragment replica is on node 3, and its backup fragment replica is on node 4.

- Partition 2 is stored on node group 0. However, the placing of its two fragment replicas is reversed from that of Partition 0; for Partition 2, the primary fragment replica is stored on node 2, and the backup on node 1.

- Partition 3 is stored on node group 1, and the placement of its two fragment replicas are reversed from those of partition 1. That is, its primary fragment replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.
In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of `ndbd`. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster “alive”. However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

The maximum number of node groups supported for a single NDB Cluster instance is 48.

### 25.2.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 25.6.11, “NDB Cluster Disk Data Tables”, for more information about these.) You can obtain information about memory usage by data nodes by viewing the `ndbinfo.memoryusage` table, or the output of the `REPORT MemoryUsage` command in the `ndb_mgm` client. For information about memory used by NDB tables, you can query the `ndbinfo.memory_per_fragment` table.

Increasing the number of CPUs, using faster CPUs, or both, on the computers hosting data nodes can generally be expected to enhance the performance of NDB Cluster. Memory requirements for cluster processes other than the data nodes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at https://dev.mysql.com/downloads/cluster/.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a protected network. If you intend to use NDB Cluster for Web applications, the cluster should
definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

Efficiency. Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

Network communication and latency. NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node’s data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node’s slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

25.2.4 What is New in MySQL NDB Cluster 8.4

- What is New in NDB Cluster 8.4
- Changes in NDB 8.x Innovation Releases
What is New in MySQL NDB Cluster 8.4

The following sections describe changes in the implementation of MySQL NDB Cluster in NDB Cluster 8.4.0, as compared to earlier release series. NDB Cluster 8.4 is available as a Development release for preview and testing of new features currently under development. For production, please use NDB 8.0; for more information, see MySQL NDB Cluster 8.0. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production, although we recommend that new deployments for production use MySQL NDB Cluster 8.0.

NDB Cluster 7.4 and 7.3 were previous GA releases which have reached their end of life; they are no longer supported or maintained.

What is New in NDB Cluster 8.4

Major changes and new features in NDB Cluster 8.4 which are likely to be of interest are listed here:

- ndbinfo transporter_details table. The transporter_details table provides information about individual transporters used in an NDB cluster. It is otherwise similar to the ndbinfo transporters table, which provides such information in aggregate form.

  NDB 8.4.0 provides additional columns as compared to the version introduced in NDB 8.0. These new columns, along with brief descriptions of each, are listed here:

  - sendbuffer_used_bytes: Number of bytes of signal data currently stored pending send using this transporter.
  - sendbuffer_max_used_bytes: Historical maximum number of bytes of signal data stored pending send using this transporter. Reset when the transporter connects.
  - sendbuffer_alloc_bytes: Number of bytes of send buffer currently allocated to store pending send bytes for this transporter. Send buffer memory is allocated in large blocks which may be sparsely used.
  - sendbuffer_max_alloc_bytes: Historical maximum number of bytes of send buffer allocated to store pending send bytes for this transporter.

  NDB 8.4.1 adds a type column, which displays the transport's connection type (TCP or SHM). See Section 25.6.17.65, "The ndbinfo transporter_details Table", for more information.

- NDB Replication: Filtering of unused updates. Previously, when SQL nodes performing binary logging used log_replica_updates=OFF, any replicated updates which were applied on a replica NDB cluster were sent on to the SQL nodes performing binary logging. These updates were not actually applied or used for any other purpose; this entailed unnecessary network traffic and consumption of resources.

  In NDB 8.4 and later, updates applied on the replica SQL node are filtered out on this node, and are no longer sent onward to any other SQL nodes. Updates that do not trigger any logging are also no longer sent by the replica.

MySQL Cluster Manager has an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See MySQL Cluster Manager 8.4.1 User Manual, for more information.

Changes in NDB 8.x Innovation Releases

New features and major changes in NDB Cluster Innovation releases (8.1, 8.2, 8.3) compared with NDB 8.0 which are likely to be of interest are listed here:

- TLS for cluster node communications. NDB Cluster 8.3 and later provides support for network communications secured by Transport Layer Security (TLS) and Internet Public Key Infrastructure (PKI) to authenticate and encrypt connections between NDB nodes, and between the NDB management server and its clients; TLS is applied to the NDB Transporter Protocol, and to the NDB Management Protocol.
This feature uses TLS mutual authentication, in which a node's own certificate file contains the chain of trust which the node uses to validate the certificates of its peers. When TLS is enabled on the cluster, data and management nodes use TLS to perform the following tasks:

- Mutually authenticate NDB clients and servers at the network level, preventing unprivileged access as a client or server
- Encrypt data transfer, avoiding data eavesdropping, modification, and man-in-the-middle attacks

Connections that use the MySQL client protocol employ MySQL user authentication, and may use TLS (including optional mutual TLS) as described elsewhere in this Manual; see Section 8.3, “Using Encrypted Connections”, for more information.

NDB implements a new tool ndb_sign_keys which can be used to create and manage CA, certificate files, and keys. You can generate a set of keys and certificates for all nodes in a cluster with a given configuration file using ndb_sign_keys --create-key.

Using ndb_sign_keys, a node certificate can be bound to a particular hostname, made to expire on a given date, and be associated with a given node type, so that clients are distinct from servers, and management servers from data nodes. (Every NDB TLS certificate can be used for MGM client connections.) Private keys are created in place, so that copying of files containing private keys is minimized. Both private keys and certificates are labeled as either active or pending; ndb_sign_keys also provides help with rotating keys to allow for pending keys to replace active keys before the active keys expire.

Testing of node TLS connections can be done from the system shell using ndb_mgm client with --test-tls, or within the ndb_mgm client using the TLS INFO command. You can obtain information about certificates used by cluster nodes by checking the ndbinfo certificates table.

To enforce a requirement for TLS, set the client option ndb-mgm-tls=strict in my.cnf on each cluster host, then set RequireTls=true in the [mgm default] section of the cluster config.ini file, and set RequireTls=true in the [ndbd default] section of the configuration file as well. Then perform a rolling restart of the cluster, restarting the management server with --reload--config-file.

Use of TLS connections is also supported in NDB Cluster API applications in NDB 8.3 and later. For information about MGM API support, see TLS Functions. The NDB API Ndb_cluster_connection class adds configure_tls() get_tls_certificate_path() methods for setting up TLS connections by clients.

For more information, see Section 25.6.15, “TLS Link Encryption for NDB Cluster”, as well as Section 25.5.28, “ndb_sign_keys — Create, Sign, and Manage TLS Keys and Certificates for NDB Cluster”.

- Binary log injector memory allocation. In previous versions of NDB Cluster, when the NDB binary log injector was engaged in handling schema changes and tracking the state of the binary log, the choice of arena for allocation of memory for these purposes was forced by changing thread local pointers, thus attempting to try and catch all allocations performed during epoch processing. At the end of the epoch, those pointers were reset, arena memory was released, and the arena structures discarded; this released the memory, but also required setting it up again for the next epoch. The thread local pointer changes also introduced the risk of memory being allocated wrongly when activating functionality in different subsystems. MySQL NDB Cluster 8.3 makes the following improvements to this functionality:
  - Changes to thread local pointers are removed, and replaced by explicit arguments to provide the arena used for allocation during the epoch.
• Re-use of the arena for next epoch, thus avoiding the need to set it up repeatedly.

These changes are internal only but should provide a noticeable improvement by saving on memory release and re-allocation over successive epochs.

• **NDB API primary key updates.** Previously, when using any other mechanism than `NdbRecord` in an attempt to update a primary key value, the NDB API returned error 4202 `Set value on tuple key attribute is not allowed`, even setting a value identical to the existing one. In NDB 8.1 and later, checking when performing updates by other means is handed off to the data nodes, as it was already when using `NdbRecord` to perform the update.

This means that you can now perform primary key updates using `NdbOperation::setValue()`, `NdbInterpretedCode::write_attr()`, and other methods of `NdbOperation` and `NdbInterpretedCode` which set column values (including the `NdbOperation` methods `incValue()`, `subValue()`, the `NdbInterpretedCode` methods `add_val()`, `sub_val()`, and so on). This also applies to the `NdbOperation` interface’s `OperationOptions::OO_SETVALUE` extension.

• **Improved warnings.** Made the following improvements in warning output:

  • The maximum time allowed without any progress is now also printed in addition to local checkpoint (LCP) elapsed time.

  • When an LCP reaches `WAIT_END_LCP` state, table IDs and fragment IDs are undefined and so no longer relevant; for this reason, we no longer attempt to print them at that point.

  • Removed duplicated information printed when the maximum limit was reached (the same information was shown as both warning and crash information).

In addition, we no longer print the message `Validating excluded objects` to the SQL node’s error log every `ndb_metadata_check_interval` (default 60) seconds when `log_error_verbosity` is greater than or equal to 3 (INFO level), due to the fact that such messages tended to flood the error log, making it difficult to examine, and using excess disk space, while not providing any additional benefit to the user.

• Pushdown joins between queries featuring very large and possibly overlapping `IN()` and `NOT IN()` lists are now handled in a correct and safe manner.

• `ndbcluster` plugin log messages now use `SYSTEM` as the log level and `NDB` as the subsystem for logging. This means that informational messages from the `ndbcluster` plugin are always printed; their verbosity can be controlled by using `--ndb_extra_logging`.

### 25.2.5 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.4

- **Parameters Introduced in NDB 8.4**
- **Parameters Deprecated in NDB 8.4**
- **Parameters Removed in NDB 8.4**
- **Options and Variables Introduced in NDB 8.4**
- **Options and Variables Deprecated in NDB 8.4**
- **Options and Variables Removed in NDB 8.4**

The next few sections contain information about NDB node configuration parameters and NDB-specific `mysql` options and variables that have been added to, deprecated in, or removed from NDB 8.4 since NDB 8.0.
Parameters Introduced in NDB 8.4

The following node configuration parameters have been added in NDB 8.4.

- **RequireCertificate**: Node is required to find key and certificate in TLS search path. Added in NDB 8.3.0.
- **RequireLinkTls**: Read-only; is set to true if either endpoint of this connection requires TLS. Added in NDB 8.3.0.
- **RequireTls**: Client connection must authenticate with TLS before being used otherwise. Added in NDB 8.3.0.
- **RequireTls**: Require TLS-authenticated secure connections. Added in NDB 8.3.0.

Parameters Deprecated in NDB 8.4

No node configuration parameters have been deprecated in NDB 8.4.

Parameters Removed in NDB 8.4

No node configuration parameters have been removed in NDB 8.4.

Options and Variables Introduced in NDB 8.4

The following system variables, status variables, and server options have been added in NDB 8.4.

- **ndb-mgm-tls**: Whether TLS connection requirements are strict or relaxed. Added in NDB 8.3.0-ndb-8.3.0.
- **ndb-tls-search-path**: Directories to search for NDB TLS CAs and private keys. Added in NDB 8.3.0-ndb-8.3.0.

Options and Variables Deprecated in NDB 8.4

No system variables, status variables, or server options have been deprecated in NDB 8.4.

Options and Variables Removed in NDB 8.4

No system variables, status variables, or options have been removed in NDB 8.4.

25.2.6 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both **NDB** and **InnoDB** can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see **NDB** as a possible alternative or upgrade to the default **InnoDB** storage engine in MySQL. While **NDB** and **InnoDB** share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the **NDB** storage engine used by NDB 8.4 with **InnoDB** used in MySQL 8.4. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for **NDB** as opposed to **InnoDB** back ends.

NDB Cluster 8.4 uses a **mysqld** based on MySQL 8.4, including support for **InnoDB** 1.1. While it is possible to use **InnoDB** tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 8.4 distribution with MySQL Server 8.4, or the reverse.
While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the InnoDB storage engine), there are some important architectural and implementation differences. Section 25.2.6.1, “Differences Between the NDB and InnoDB Storage Engines”, provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 25.2.6.2, “NDB and InnoDB Workloads”. This in turn has an impact on the types of applications that better suited for use with NDB or InnoDB. See Section 25.2.6.3, “NDB and InnoDB Feature Usage Summary”, for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the NDB and MEMORY storage engines, see When to Use MEMORY or NDB Cluster.

See Chapter 18, Alternative Storage Engines, for additional information about MySQL storage engines.

### 25.2.6.1 Differences Between the NDB and InnoDB Storage Engines

The NDB storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from InnoDB in a number of ways. For those unaccustomed to working with NDB, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

#### Table 25.1 Differences between InnoDB and NDB storage engines

<table>
<thead>
<tr>
<th>Feature</th>
<th>InnoDB (MySQL 8.4)</th>
<th>NDB 8.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL Server Version</td>

</table>
### 25.2.6.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table:

<table>
<thead>
<tr>
<th>Workload</th>
<th>InnoDB</th>
<th>NDB Cluster (NDB)</th>
</tr>
</thead>
<tbody>
<tr>

25.2.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

Table 25.3 Supported application features according to the storage engine to which each feature is typically better suited

<table>
<thead>
<tr>
<th>Preferred application requirements for InnoDB</th>

25.2.7 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the “Cluster” category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at http://bugs.mysql.com, which we intend to correct in upcoming releases of NDB Cluster:

• NDB Cluster
• Cluster Direct API (NDBAPI)
• Cluster Disk Data
• Cluster Replication
• ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”. Any problem which we do not plan to fix in NDB Cluster 8.4, is added to the list.

See Section 25.2.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.4” for a list of issues in earlier releases that have been resolved in NDB Cluster 8.4.

Note

Limitations and other issues specific to NDB Cluster Replication are described in Section 25.7.3, “Known Issues in NDB Cluster Replication”.

3800
### 25.2.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with NDB tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the NDB storage engine or to alter an existing temporary table to use NDB fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.

- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an NDB table column whose width is greater than 3072 bytes is rejected with `ER_TOO_LONG_KEY: Specified key was too long; max key length is 3072 bytes`.

  Attempting to create an index on an NDB table column whose width is greater than 3056 bytes succeeds with a warning. In such cases, statistical information is not generated, which means a nonoptimal execution plan may be selected. For this reason, you should consider making the index length shorter than 3056 bytes if possible.

  - **TEXT and BLOB columns.** You cannot create indexes on NDB table columns that use any of the TEXT or BLOB data types.

  - **FULLTEXT indexes.** The NDB storage engine does not support FULLTEXT indexes, which are possible for MyISAM and InnoDB tables only.

  However, you can create indexes on VARCHAR columns of NDB tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.

- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an NDB column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 25.2.7.6, "Unsupported or Missing Features in NDB Cluster", for additional information.)

- **BIT columns.** A BIT column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.

- **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one AUTO_INCREMENT column per table, and this column must be indexed. However, in the case of an NDB table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a "hidden" primary key. For this reason, you cannot create an NDB table having an AUTO_INCREMENT column and no explicit primary key.

The following `CREATE TABLE` statements do not work, as shown here:

```sql
# No index on AUTO_INCREMENT column; table has no primary key
# Raises ER_WRONG_AUTO_KEY
mysql> CREATE TABLE n {
  ->   a INT,
  ->   b INT AUTO_INCREMENT
  -> }
  -> ENGINE=NDB;
ERROR 1075 (42000): Incorrect table definition; there can be only one auto column and it must be defined as a key

# Index on AUTO_INCREMENT column; table has no primary key
# Raises NDB error 4335
mysql> CREATE TABLE n {
```
Known Limitations of NDB Cluster

```sql
CREATE TABLE n (
    a INT PRIMARY KEY,
    b INT AUTO_INCREMENT,
    KEY k (b)
) ENGINE=NDB;
```

ERROR 1296 (HY000): Got error 4335 'Only one autoincrement column allowed per table. Having a table without primary key uses an autoincr' from NDBCLUSTER

The following statement creates a table with a primary key, an AUTO_INCREMENT column, and an index on this column, and succeeds:

```sql
# Index on AUTO_INCREMENT column; table has a primary key
mysql> CREATE TABLE n (
    -> a INT PRIMARY KEY,
    -> b INT AUTO_INCREMENT,
    -> KEY k (b)
    -> }
    -> ENGINE=NDB;
Query OK, 0 rows affected (0.38 sec)
```

- **Restrictions on foreign keys.** Support for foreign key constraints in NDB 8.4 is comparable to that provided by InnoDB, subject to the following restrictions:

  - Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.

  - **ON UPDATE CASCADE** is not supported when the reference is to the parent table’s primary key.
    
    This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the NDB kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.

  - **ON DELETE CASCADE** is also not supported where the child table contains one or more columns of any of the TEXT or BLOB types. (Bug #89511, Bug #27484882)

  - **SET DEFAULT** is not supported. (Also not supported by InnoDB.)

  - The **NO ACTION** keyword is accepted but treated as **RESTRICT.NO ACTION**, which is a standard SQL keyword, is the default in MySQL 8.4. (Also the same as with InnoDB.)

  - In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most cases; however, it remains possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

For more information, see Section 15.1.20.5, “FOREIGN KEY Constraints”, and Section 1.7.3.2, “FOREIGN KEY Constraints”.

- **NDB Cluster and geometry data types.** Geometry data types (WKT and WKB) are supported for NDB tables. However, spatial indexes are not supported.

- **Character sets and binary log files.** Currently, the ndb_apply_status and ndb_binlog_index tables are created using the latin1 (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the --basedir, --log-bin, or --log-bin-index options.
**Known Limitations of NDB Cluster**

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning in NDB Cluster is restricted to [LINEAR] KEY partitioning. Using any other partitioning type with ENGINE=NDB or ENGINE=NDBCLUSTER in a CREATE TABLE statement results in an error.

  It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see User-defined partitioning and the NDB storage engine (NDB Cluster).

- **Default partitioning scheme.** All NDB Cluster tables are by default partitioned by KEY using the table’s primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the NDB storage engine is used instead. For additional discussion of these and related issues, see Section 26.2.5, “KEY Partitioning”.

  CREATE TABLE and ALTER TABLE statements that would cause a user-partitioned NDBCLUSTER table not to meet either or both of the following two requirements are not permitted, and fail with an error:

  1. The table must have an explicit primary key.
  2. All columns listed in the table’s partitioning expression must be part of the primary key.

- **Exception.** If a user-partitioned NDBCLUSTER table is created using an empty column-list (that is, using PARTITION BY [LINEAR] KEY()), then no explicit primary key is required.

- **Maximum number of partitions for NDBCLUSTER tables.** The maximum number of partitions that can defined for a NDBCLUSTER table when employing user-defined partitioning is 8 per node group. (See Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”, for more information about NDB Cluster node groups.

- **DROP PARTITION not supported.** It is not possible to drop partitions from NDB tables using ALTER TABLE ... DROP PARTITION. The other partitioning extensions to ALTER TABLE—ADD PARTITION, REORGANIZE PARTITION, and COALESCE PARTITION—are supported for NDB tables, but use copying and so are not optimized. See Section 26.3.1, “Management of RANGE and LIST Partitions” and Section 15.1.9, “ALTER TABLE Statement”.

- **Partition selection.** Partition selection is not supported for NDB tables. See Section 26.5, “Partition Selection”, for more information.

- **JSON data type.** The MySQL JSON data type is supported for NDB tables in the mysqld supplied with NDB 8.4.

  An NDB table can have a maximum of 3 JSON columns.

  The NDB API has no special provision for working with JSON data, which it views simply as BLOB data. Handling data as JSON must be performed by the application.

**25.2.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits**

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

- **Memory usage and recovery.** Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

  - A DELETE statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing OPTIMIZE TABLE.

  A rolling restart of the cluster also frees any memory used by deleted rows. See Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”.

  3803
Known Limitations of NDB Cluster

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

  **Note**
  Recall that `TRUNCATE TABLE` drops and re-creates the table. See Section 15.1.37, "TRUNCATE TABLE Statement".

- **Limits imposed by the cluster's configuration.**
  A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 25.4.3, "NDB Cluster Configuration Files". Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).
    `DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.
    See Section 25.4.3.6, "Defining NDB Cluster Data Nodes", for more information.

  - The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.
    **Note**
    Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

  - Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.

  - **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:
    - The maximum number of data nodes is 144. (In NDB 7.6 and earlier, this was 48.)
      A data node must have a node ID in the range of 1 to 144, inclusive.
      Management and API nodes may use node IDs in the range 1 to 255, inclusive.
    - The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
    - The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.
    See Section 25.2.7.11, "Previous NDB Cluster Issues Resolved in NDB Cluster 8.4", for more information.

25.2.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (InnoDB, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) You should keep in mind that NDB
Known Limitations of NDB Cluster

implements **READ COMMITTED** on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using **SELECT ... LOCK IN SHARE MODE**. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

- Increased frequency of lock wait timeout errors, and reduced concurrency
- Increased transaction processing overhead due to reads requiring a commit phase
- Possibility of exhausting the available number of concurrent locks, which is limited by **MaxNoOfConcurrentOperations**

**NDB** uses **READ COMMITTED** for all reads unless a modifier such as **LOCK IN SHARE MODE** or **FOR UPDATE** is used. **LOCK IN SHARE MODE** causes shared row locks to be used; **FOR UPDATE** causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by **NDB** to ensure a self-consistent read; **BLOB** reads also employ extra locking for consistency.

See Section 25.6.8.4, “NDB Cluster Backup Troubleshooting”, for information on how NDB Cluster’s implementation of transaction isolation level can affect backup and restoration of **NDB** databases.

- **Transactions and BLOB or TEXT columns.** **NDBCLUSTER** stores only part of a column value that uses any of **MySQL**’s **BLOB** or **TEXT** data types in the table visible to **MySQL**; the remainder of the **BLOB** or **TEXT** is stored in a separate internal table that is not accessible to **MySQL**. This gives rise to two related issues of which you should be aware whenever executing **SELECT** statements on tables that contain columns of these types:

  1. For any **SELECT** from an NDB Cluster table: If the **SELECT** includes a **BLOB** or **TEXT** column, the **READ COMMITTED** transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

  2. For any **SELECT** which uses a unique key lookup to retrieve any columns that use any of the **BLOB** or **TEXT** data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against **NDB** tables having **BLOB** or **TEXT** columns.

For example, consider the table **t** defined by the following **CREATE TABLE** statement:

```sql
CREATE TABLE t (  
a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
b INT NOT NULL,  
c INT NOT NULL,  
d TEXT,  
INDEX i(b),  
UNIQUE KEY u(c)  
) ENGINE = NDB,
```

The following query on **t** causes a shared read lock, because it uses a unique key lookup:

```sql
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```sql
SELECT * FROM t WHERE b = 1;
```
Known Limitations of NDB Cluster

```
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any BLOB or TEXT columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve BLOB or TEXT columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Unique key lookups and transaction isolation.** Unique indexes are implemented in NDB using a hidden index table which is maintained internally. When a user-created NDB table is accessed using a unique index, the hidden index table is first read to find the primary key that is then used to read the user-created table. To avoid modification of the index during this double-read operation, the row found in the hidden index table is locked. When a row referenced by a unique index in the user-created NDB table is updated, the hidden index table is subject to an exclusive lock by the transaction in which the update is performed. This means that any read operation on the same (user-created) NDB table must wait for the update to complete. This is true even when the transaction level of the read operation is READ COMMITTED.

One workaround which can be used to bypass potentially blocking reads is to force the SQL node to ignore the unique index when performing the read. This can be done by using the IGNORE INDEX index hint as part of the SELECT statement reading the table (see Section 10.9.4, “Index Hints”). Because the MySQL server creates a shadowing ordered index for every unique index created in NDB, this lets the ordered index be read instead, and avoids unique index access locking. The resulting read is as consistent as a committed read by primary key, returning the last committed value at the time the row is read.

Reading via an ordered index makes less efficient use of resources in the cluster, and may have higher latency.

It is also possible to avoid using the unique index for access by querying for ranges rather than for unique values.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as InnoDB that may roll back individual statements.

- **Transactions and memory usage.**
  As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

  - **TRUNCATE TABLE** is not transactional when used on NDB tables. If a TRUNCATE TABLE fails to empty the table, then it must be re-run until it is successful.

  - **DELETE FROM** (even with no WHERE clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several DELETE FROM ...
**Known Limitations of NDB Cluster**

- **LIMIT ...** statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use **TRUNCATE TABLE** instead.

- **LOAD DATA statements.** **LOAD DATA** is not transactional when used on **NDB** tables.

  **Important**
  When executing a **LOAD DATA** statement, the **NDB** engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

- **ALTER TABLE and transactions.** When copying an **NDB** table as part of an **ALTER TABLE**, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

- **Transactions and the COUNT() function.** When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the **COUNT()** function on the replica. In other words, when performing on the source a series of statements (**INSERT**, **DELETE**, or both) that changes the number of rows in a table within a single transaction, executing **SELECT COUNT(*) FROM table** queries on the replica may yield intermediate results. This is due to the fact that **SELECT COUNT(...)** may perform dirty reads, and is not a bug in the **NDB** storage engine. (See Bug #31321 for more information.)

### 25.2.7.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 **Temporary failure, distribution changed** and similar temporary errors.

- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

  In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

  See also Section 25.2.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”.

### 25.2.7.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the **NDBCLUSTER** storage engine:

- **Number of database objects.** The maximum number of **all NDB** database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.

- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.

- **Attributes per key.** The maximum number of attributes per key is 32.

- **Row size.** The maximum permitted size of any one row is 30000 bytes.

  Each **BLOB** or **TEXT** column contributes 256 + 8 = 264 bytes to this total; this includes **JSON** columns. See **String Type Storage Requirements**, as well as **JSON Storage Requirements**, for more information relating to these types.

  In addition, the maximum offset for a fixed-width column of an **NDB** table is 8188 bytes; attempting to create a table that violates this limitation fails with NDB error 851 **Maximum offset for**
Known Limitations of NDB Cluster

known_limitations_of_ndb_cluster

For memory-based columns, you can work around this limitation by using a variable-width column type such as VARCHAR or defining the column as COLUMN_FORMAT=DYNAMIC; this does not work with columns stored on disk. For disk-based columns, you may be able to do so by reordering one or more of the table’s disk-based columns such that the combined width of all but the disk-based column defined last in the CREATE TABLE statement used to create the table does not exceed 8188 bytes, less any possible rounding performed for some data types such as CHAR or VARCHAR; otherwise it is necessary to use memory-based storage for one or more of the offending column or columns instead.

- BIT column storage per table.  The maximum combined width for all BIT columns used in a given NDB table is 4096.

- FIXED column storage.  NDB Cluster supports a maximum of 128 TB per fragment of data in FIXED columns.

25.2.7.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by NDB, must be syntactically and otherwise valid.

- Index prefixes.  Prefixes on indexes are not supported for NDB tables. If a prefix is used as part of an index specification in a statement such as CREATE TABLE, ALTER TABLE, or CREATE INDEX, the prefix is not created by NDB.

A statement containing an index prefix, and creating or modifying an NDB table, must still be syntactically valid. For example, the following statement always fails with Error 1089 incorrect prefix key; the used key part is not a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys, regardless of storage engine:

```
CREATE TABLE t1 {
  c1 INT NOT NULL,
  c2 VARCHAR(100),
  INDEX i1 (c2(500))
};
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- Savepoints and rollbacks.  Savepoints and rollbacks to savepoints are ignored as in MyISAM.

- Durability of commits.  There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- Replication.  Statement-based replication is not supported. Use --binlog-format=ROW (or --binlog-format=MIXED) when setting up cluster replication. See Section 25.7, “NDB Cluster Replication”, for more information.

Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 8.4. Do not enable GTIDs when using the NDB storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

Semisynchronous replication is not supported in NDB Cluster.

- Generated columns.  The NDB storage engine does not support indexes on virtual generated columns.

As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that NDB uses DataMemory for storage of the generated column as well as IndexMemory for the index. See JSON columns and indirect indexing in NDB Cluster, for an example.
NDB Cluster writes changes in stored generated columns to the binary log, but does log not those made to virtual columns. This should not effect NDB Cluster Replication or replication between NDB and other MySQL storage engines.

Note
See Section 25.2.7.3, “Limits Relating to Transaction Handling in NDB Cluster”, for more information relating to limitations on transaction handling in NDB.

25.2.7.7 Limitations Relating to Performance in NDB Cluster
The following performance issues are specific to or especially pronounced in NDB Cluster:

• Range scans. There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.

• Reliability of Records in range. The Records in range statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ USE INDEX or FORCE INDEX to alter the execution plan. See Section 10.9.4, “Index Hints”, for more information on how to do this.

• Unique hash indexes. Unique hash indexes created with USING HASH cannot be used for accessing a table if NULL is given as part of the key.

25.2.7.8 Issues Exclusive to NDB Cluster
The following are limitations specific to the NDB storage engine:

• Machine architecture. All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running mysql or other clients that may be accessing the cluster’s SQL nodes.

• Binary logging.
NDB Cluster has the following limitations or restrictions with regard to binary logging:

• NDB Cluster cannot produce a binary log for tables having BLOB columns but no primary key.

• Only the following schema operations are logged in a cluster binary log which is not on the mysqld executing the statement:

  • CREATE TABLE
  • ALTER TABLE
  • DROP TABLE
  • CREATE DATABASE / CREATE SCHEMA
  • DROP DATABASE / DROP SCHEMA
  • CREATE TABLESPACE
  • ALTER TABLESPACE
  • DROP TABLESPACE
  • CREATE LOGFILE GROUP
  • ALTER LOGFILE GROUP
Known Limitations of NDB Cluster

- **DROP LOGFILE GROUP**

- **Schema operations.** Schema operations (DDL statements) are rejected while any data node restarts. Schema operations are also not supported while performing an online upgrade or downgrade.

- **Number of fragment replicas.** The number of fragment replicas, as determined by the `NoOfReplicas` data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

  Setting `NoOfReplicas` to a value greater than 2 is supported (to a maximum of 4) but unnecessary to guard against loss of data.

See also Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### 25.2.7.9 Limitations Relating to NDB Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: $2^{32}$ (4294967296)
- Maximum number of data files per tablespace: $2^{16}$ (65536)
- The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 15.1.21, “CREATE TABLESPACE Statement”, for more information.

In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:

- Data files use `DataMemory`. Usage is the same as for in-memory data.
- Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.
- Extents require sufficient `DiskPageBufferMemory`; you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode.

### 25.2.7.10 Limitations Relating to Multiple NDB Cluster Nodes

**Multiple SQL nodes.** The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **Stored programs not distributed.** Stored procedures, stored functions, triggers, and scheduled events are all supported by tables using the `NDB` storage engine, but these do not propagate automatically between MySQL Servers acting as Cluster SQL nodes, and must be re-created separately on each SQL node. See Stored routines and triggers in NDB Cluster.

- **No distributed table locks.** A `LOCK TABLES` statement or `GET_LOCK()` call works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

  Implementing table locks in `NDBCLUSTER` can be done in an API application, and ensuring that all applications start by setting `LockMode` to `LM_Read` or `LM_Exclusive`. For more information about
how to do this, see the description of NdbOperation::getLockHandle() in the NDB Cluster API Guide.

- ALTER TABLE operations. ALTER TABLE is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

Multiple management nodes.
When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.

- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server --reload and --initial startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

Note
It is possible to use multiple network hardware interfaces (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one [tcp] section per connection in the config.ini file. See Section 25.4.3.10, “NDB Cluster TCP/IP Connections”, for more information.

25.2.7.11 Previous NDB Cluster Issues Resolved in NDB Cluster 8.4

A number of limitations and related issues that existed in earlier versions of NDB Cluster have been resolved in NDB 8.4. These are described briefly in the following list:

- Issue now resolved... Text...

More text...

25.3 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in Section 25.4, “Configuration of NDB Cluster” provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the minimum requirements for availability and safeguarding of data.

For information about upgrading or downgrading an NDB Cluster between release versions, see Section 25.3.7, “Upgrading and Downgrading NDB Cluster”.

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.
Assumptions. The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

Table 25.4 Network addresses of nodes in example cluster

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node</td>
<td>198.51.100.10</td>
</tr>
<tr>
<td>SQL node</td>
<td>198.51.100.20</td>
</tr>
<tr>
<td>Data node &quot;A&quot;</td>
<td>198.51.100.30</td>
</tr>
<tr>
<td>Data node &quot;B&quot;</td>
<td>198.51.100.40</td>
</tr>
</tbody>
</table>

This setup is also shown in the following diagram:

Figure 25.4 NDB Cluster Multi-Computer Setup

Network addressing. In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the hosts file (typically /etc/hosts for Linux and other Unix-like operating systems, C:\WINDOWS\system32\drivers\etc \hosts on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

NDB 8.4 supports IPv6 for connections between all NDB Cluster nodes.

Potential hosts file issues. A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the /etc/hosts during installation. Consider two machines with the host names ndb1 and ndb2, both in the cluster network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' /etc/hosts files:

```
# ndb1 /etc/hosts:
127.0.0.1 ndb1.cluster ndb1 localhost.localdomain localhost
```
Installation of NDB Cluster on Linux

SUSE Linux (including OpenSUSE) places these entries in the machines’ /etc/hosts files:

```
# ndb1 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb1.cluster ndb1

# ndb2 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb2.cluster ndb2
```

In both instances, ndb1 routes ndb1.cluster to a loopback IP address, but gets a public IP address from DNS for ndb1.cluster, while ndb2 routes ndb2.cluster to a loopback address and obtains a public address for ndb2.cluster. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

**Caution**

You cannot mix localhost and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for `all config.ini HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

**Important**

NDB Cluster is not intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the `world` database which is available for download from the MySQL website (see https://dev.mysql.com/doc/index-other.html). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, *Installing MySQL*. For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see Section 25.3.1, “Installation of NDB Cluster on Linux”. For information about installation of NDB Cluster on Windows operating systems, see Section 25.3.2, “Installing NDB Cluster on Windows”.

For general information about NDB Cluster hardware, software, and networking requirements, see Section 25.2.3, “NDB Cluster Hardware, Software, and Networking Requirements”.

**25.3.1 Installation of NDB Cluster on Linux**
This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see Section 25.3.2, “Installing NDB Cluster on Windows”.

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (mysqld). Management nodes require the management server daemon (ndb_mgmd); data nodes require the data node daemon (ndbd or ndbmd). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (ndb_mgm) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 25.3.3, “Initial Configuration of NDB Cluster”.

25.3.1.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

By setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the NDB Cluster downloads page. (For the most recent 64-bit NDB 8.4 release, this is mysql-cluster-gpl-8.4.0-linux-glibc2.12-x86_64.tar.gz.) We assume that you have placed this file in each machine’s /var/tmp directory.

If you require a custom binary, see Section 2.8.5, “Installing MySQL Using a Development Source Tree”.

Note
After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 25.3.3, “Initial Configuration of NDB Cluster”).

SQL nodes. On each of the machines designated to host SQL nodes, perform the following steps as the system root user:

1. Check your /etc/passwd and /etc/group files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a mysql group and mysql user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new mysql user group, and then add a mysql user to this group:

```bash
$> groupadd mysql
$> useradd -g mysql -s /bin/false mysql
```

The syntax for useradd and groupadd may differ slightly on different versions of Unix, or they may have different names such as adduser and addgroup.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named mysql to the mysql directory.

Note
The actual file and directory names vary according to the NDB Cluster version number.
### Installation of NDB Cluster on Linux

1. **Change location to the `/var/tmp` directory and extract the `ndbd` and `ndbmtd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

   ```
   $> cd /var/tmp
   $> tar -xzf mysql-cluster-gpl-8.4.0-linux-glibc2.12-x86_64.tar.gz
   $> cd mysql-cluster-gpl-8.4.0-linux-glibc2.12-x86_64
   $> cp bin/ndbd /usr/local/bin/ndbd
   $> cp bin/ndbmtd /usr/local/bin/ndbmtd
   ```

   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. **Change location to the directory into which you copied the files, and then make both of them executable:**

   ```
   $> cd /usr/local/bin
   ```

3. **Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:**

   ```
   $> cd mysql
   $> mysqld --initialize
   ```

   This generates a random password for the MySQL root account. If you do not want the random password to be generated, you can substitute the `--initialize-insecure` option for `--initialize`. In either case, you should review Section 2.9.1, “Initializing the Data Directory”, for additional information before performing this step. See also Section 6.4.2, “mysql_secure_installation — Improve MySQL Installation Security”.

4. **Set the necessary permissions for the MySQL server and data directories:**

   ```
   $> chown -R root .
   $> chOWN -R mysql data
   $> chgrp -R mysql .
   ```

5. **Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:**

   ```
   $> cp support-files/mysql.server /etc/rc.d/init.d/
   $> chmod +x /etc/rc.d/init.d/mysql.server
   $> chkconfig --add mysql.server
   ```

   (The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

   Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

### Data nodes

Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmtd` (multithreaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo, su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. **Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

   ```
   $> cd /var/tmp
   $> tar -xzf mysql-cluster-gpl-8.4.0-linux-glibc2.12-x86_64.tar.gz
   $> cd mysql-cluster-gpl-8.4.0-linux-glibc2.12-x86_64
   $> cp bin/ndbd /usr/local/bin/ndbd
   $> cp bin/ndbmtd /usr/local/bin/ndbmtd
   ```

   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. **Change location to the directory into which you copied the files, and then make both of them executable:**

   ```
   $> cd /usr/local/bin
   ```
Installation of NDB Cluster on Linux

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both ndbd and ndbmtd in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this saves time and trouble in the event that you later decide to change from one to the other.

Note

The data directory on each machine hosting a data node is /usr/local/mysql/data. This piece of information is essential when configuring the management node. (See Section 25.3.3, “Initial Configuration of NDB Cluster”.)

Management nodes. Installation of the management node does not require the mysqlld binary. Only the NDB Cluster management server (ndb_mgmd) is required; you most likely want to install the management client (ndb_mgm) as well. Both of these binaries are also found in the .tar.gz archive. Again, we assume that you have placed this archive in /var/tmp.

As system root, perform the following steps to install ndb_mgm and ndb_mgmd on the management node host:

1. Change location to the /var/tmp directory, and extract the ndb_mgm and ndb_mgmd from the archive into a suitable directory such as /usr/local/bin:

   ```
   $> cd /var/tmp
   $> tar -zxvf mysql-cluster-gpl-8.4.0-linux-glibc2.12-x86_64.tar.gz
   $> cd mysql-cluster-gpl-8.4.0-linux-glibc2.12-x86_64
   $> cp bin/ndb_mgm* /usr/local/bin
   ```

   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from /var/tmp once ndb_mgm and ndb_mgmd have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

   ```
   $> cd /usr/local/bin
   $> chmod +x ndb_mgm*
   ```

   In Section 25.3.3, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

25.3.1.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster node using RPM packages supplied by Oracle.

As an alternative to the method described in this section, Oracle provides MySQL Repositories for NDB Cluster that are compatible with many common Linux distributions. Two repositories, listed here, are available for RPM-based distributions:

- For distributions using yum or dnf, you can use the MySQL Yum Repository for NDB Cluster. See Installing MySQL NDB Cluster Using the Yum Repository, for instructions and additional information.

- For SLES, you can use the MySQL SLES Repository for NDB Cluster. See Installing MySQL NDB Cluster Using the SLES Repository, for instructions and additional information.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-community-data-node-8.4.0-1.el7.x86_64.rpm
```
Installation of NDB Cluster on Linux

```
license: {commercial | community}
component: {management-server | data-node | server | client | other—see text}
ver: major.minor.release
rev: major.[minor]
distro: {el6 | el7 | sles12}
distro: {i686 | x86_64}
```

`license` indicates whether the RPM is part of a Commercial or Community release of NDB Cluster. In the remainder of this section, we assume for the examples that you are installing a Community release.

Possible values for `component`, with descriptions, can be found in the following table:

### Table 25.5 Components of the NDB Cluster RPM distribution

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>

## Installation of NDB Cluster on Linux

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>server-minimal</td>
<td>Minimal installation of the MySQL server for NDB and related tools</td>
</tr>
<tr>
<td>test</td>
<td>mysqltest, other MySQL test programs, and support files</td>
</tr>
</tbody>
</table>

A single bundle (.tar file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```bash
download/mysql-cluster-license-ver-rev.distro.arch.rpm-bundle.tar
```

You can extract the individual RPM files from this file using `tar` or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:

- **Management node**: `management-server`
- **Data node**: `data-node`
- **SQL node**: `server` and `common`

In addition, the `client` RPM should be installed to provide the `ndb_mgm` management client on at least one management node. You may also wish to install it on SQL nodes, to have `mysql` and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

`ver` represents the three-part NDB storage engine version number in 8.4.x format, shown as `8.4.0` in the examples. `rev` provides the RPM revision number in `major.minor` format. In the examples shown in this section, we use `1.1` for this value.

The `distro` (Linux distribution) is one of `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), `el6` (Oracle Linux 6, Red Hat Enterprise Linux 6), `el7` (Oracle Linux 7, Red Hat Enterprise Linux 7), or `sles12` (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent (`el7`).

`arch` is `i686` for 32-bit RPMs and `x86_64` for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as `8.4.0`) can vary according to the version which you are actually using. **It is very important that all of the Cluster RPMs to be installed have the same version number.** The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs (`x86_64`) cannot be used with 32-bit operating systems (use `i686` for the latter).

### Data nodes

On a computer that is to host an NDB Cluster data node it is necessary to install only the `data-node` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```bash
$ rpm -Uvh mysql-cluster-community-data-node-8.4.0-1.el7.x86_64.rpm
```

This installs the `ndbd` and `ndbmd` data node binaries in `/usr/sbin`. Either of these can be used to run a data node process on this host.

### SQL nodes

Copy the `server` and `common` RPMs to each machine to be used for hosting an NDB Cluster SQL node (`server` requires `common`). Install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```bash
$ rpm -Uvh mysql-cluster-community-server-8.4.0-1.el7.x86_64.rpm
```
This installs the MySQL server binary (mysqld), with NDB storage engine support, in the /usr/sbin directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the mysql.server and mysqld_safe startup scripts (in /usr/share/mysql and /usr/bin, respectively). The RPM installer should take care of general configuration issues (such as creating the mysql user and group, if needed) automatically.

Important

You must use the versions of these RPMs released for NDB Cluster; those released for the standard MySQL server do not provide support for the NDB storage engine.

To administer the SQL node (MySQL server), you should also install the client RPM, as shown here:

```
$ rpm -Uhv mysql-cluster-community-client-8.4.0-1.el7.x86_64.rpm
```

This installs the mysql client and other MySQL client programs, such as mysqladmin and mysqldump, to /usr/bin.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the management-server RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the management-server RPM downloaded from the MySQL website):

```
$ rpm -Uhv mysql-cluster-community-management-server-8.4.0-1.el7.x86_64.rpm
```

This RPM installs the management server binary ndb_mgmd in the /usr/sbin directory. While this is the only program actually required for running a management node, it is also a good idea to have the ndb_mgm NDB Cluster management client available as well. You can obtain this program, as well as other NDB client programs such as ndb_desc and ndb_config, by installing the client RPM as described previously.

See Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”, for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see Section 25.3.3, “Initial Configuration of NDB Cluster”, for the relevant information.

It is very important that all of the Cluster RPMs to be installed have the same version number. The architecture designation should also be appropriate to the machine on which the RPM is to be installed: in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the server RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
$ rpm -Uhv MySQL-Cluster-server-gpl-8.4.0-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program ndbd or ndbmtd (both in /usr/sbin) is actually needed to run an NDB Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the server RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
$ rpm -Uhv MySQL-Cluster-server-gpl-8.4.0-1.sles11.i386.rpm
```

This installs the MySQL server binary (mysqld) with NDB storage engine support in the /usr/sbin directory, as well as all needed MySQL Server support files. It also installs the mysql.server and mysqld_safe startup scripts (in /usr/share/mysql and /usr/bin, respectively). The RPM
installer should take care of general configuration issues (such as creating the mysql user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the client RPM, as shown here:

```bash
$> rpm -Uhv MySQL-Cluster-client-gpl-8.4.0-1.sles11.i386.rpm
```

This installs the mysql client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the server RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the server RPM downloaded from the MySQL website):

```bash
$> rpm -Uhv MySQL-Cluster-server-gpl-8.4.0-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary ndb_mgmd (in the /usr/sbin directory) is actually required for running a management node. The server RPM also installs ndb_mgm, the NDB management client.

### 25.3.1.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such Ubuntu using the .deb files supplied by Oracle for this purpose.

Oracle also provides an NDB Cluster APT repository for Debian and other distributions. See [Installing MySQL NDB Cluster Using the APT Repository](#), for instructions and additional information.

Oracle provides .deb installer files for NDB Cluster for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```bash
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, ndbver is the 3-part NDB engine version number, debianver is the major version of Debian (8 or 9), and arch is one of i686 or x86_64. In the examples that follow, we assume you wish to install NDB 8.4.0 on a 64-bit Debian 9 system; in this case, the installer file is named `mysql-cluster-gpl-8.4.0-debian9-x86_64.deb-bundle.tar`.

Once you have downloaded the appropriate .deb file, you can untar it, and then install it from the command line using dpkg, like this:

```bash
$> dpkg -i mysql-cluster-gpl-8.4.0-debian9-i686.deb
```

You can also remove it using dpkg as shown here:

```bash
$> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with .deb files, such as GDebi for the Gnome desktop.

The .deb file installs NDB Cluster under `/opt/mysql/server-version/`, where version is the 2-part release series version for the included MySQL server. For NDB 8.4, this is always 8.4. The directory layout is the same as that for the generic Linux binary distribution (see Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as ndb_mgm, ndbd, and ndb_mgmd, are placed in the bin directory.

### 25.3.1.4 Building NDB Cluster from Source on Linux

---

3820
This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.8, "Installing MySQL from Source". For information about compiling NDB Cluster on Windows platforms, see Section 25.3.2.2, "Compiling and Installing NDB Cluster from Source on Windows".

MySQL NDB Cluster 8.4 is built from the MySQL Server 8.4 sources, available from the MySQL downloads page at https://dev.mysql.com/downloads/. The archived source file should have a name similar to `mysql-8.4.0.tar.gz`. You can also obtain the sources from GitHub at https://github.com/mysql/mysql-server.

The `WITH_NDB` option for CMake causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes `mysqld` to be compiled with NDB storage engine support. This option is required when building NDB Cluster.

---

**Important**

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see CMake Options for Compiling NDB Cluster.

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

**Management nodes.** When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

**Data nodes.** The only executable required on a data node host is the data node binary `ndbd` or `ndbmttd` (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmttd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with NDB storage engine support causes `ndbmttd` to be built automatically; `make install` places the `ndbmttd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

**SQL nodes.** If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system root user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Section 2.8, "Installing MySQL from Source" to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.8, "Installing MySQL from Source" on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In Section 25.3.3, "Initial Configuration of NDB Cluster", we create configuration files for all of the nodes in our example NDB Cluster.

### 25.3.2 Installing NDB Cluster on Windows
This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 8.4 binaries for Windows can be obtained from https://dev.mysql.com/downloads/cluster/. For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see Section 25.3.2.1, “Installing NDB Cluster on Windows from a Binary Release”.

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 25.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”.

### 25.3.2.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary “no-install” NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 25.3, “NDB Cluster Installation”), as shown in the following table:

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node (mgmd)</td>
<td>198.51.100.10</td>
</tr>
<tr>
<td>SQL node (mysqld)</td>
<td>198.51.100.20</td>
</tr>
<tr>
<td>Data node “A” (ndbd)</td>
<td>198.51.100.30</td>
</tr>
<tr>
<td>Data node “B” (ndbd)</td>
<td>198.51.100.40</td>
</tr>
</tbody>
</table>

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (mysqld.exe). You should also have the MySQL client (mysql.exe) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (ndb_mgmd.exe); each data node requires the data node daemon (ndbd.exe or ndbmmtd.exe). For this example, we refer to ndbd.exe as the data node executable, but you can install ndbmmtd.exe, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (ndb_mgm.exe) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

**Note**

As with other Windows programs, NDB Cluster executables are named with the .exe file extension. However, it is not necessary to include the .exe extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as mysqld, mysql, ndb_mgmd, and so on. You should understand that, whether we refer (for example) to mysqld or mysqld.exe, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle’s no-install binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from https://dev.mysql.com/downloads/cluster/. This archive has a filename of the mysql-cluster-gpl-ver-winarch.zip, where ver is the NDB storage engine version (such as 8.4.0), and arch is the architecture (32 for 32-bit binaries, and 64 for 64-bit binaries). For example, the NDB Cluster 8.4.0 archive for 64-bit Windows systems is named mysql-cluster-gpl-8.4.0-win64.zip.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the archive in the directory C:\Documents and Settings\username\My Documents\Downloads on the computer having the IP address.

3822
Installing NDB Cluster on Windows

198.51.100.20, where username is the name of the current user. (You can obtain this name using ECHO %USERNAME% on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the Administrators group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter C:\, which causes the Extraction Wizard to extract the archive to the directory C:\mysql-cluster-gpl-ver-winarch. Rename this directory to C:\mysql.

It is possible to install the NDB Cluster binaries to directories other than C:\mysql\bin; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than C:\mysql or C:\Program Files \MySQL\MySQL Server 8.4, or if the SQL node’s data directory is in a location other than C:\mysql\data or C:\Program Files\MySQL\MySQL Server 8.4\data, extra configuration options must be used on the command line or added to the my.ini or my.cnf file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.3, “Configuration: Manually”.

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options --ndbcluster and --ndb-connectstring. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                       # run NDB storage engine
ndb-connectstring=198.51.100.10  # location of management server
```

You can add other options used by this MySQL Server if desired (see Section 2.3.3.2, “Creating an Option File”), but the file must contain the options shown, at a minimum. Save this file as C:\mysql\my.ini. This completes the installation and setup for the SQL node.

Data nodes. An NDB Cluster data node on a Windows host requires only a single executable, one of either ndbd.exe or ndbmtd.exe. For this example, we assume that you are using ndbd.exe, but the same instructions apply when using ndbmtd.exe. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories C:\mysql, C:\mysql\bin, and C:\mysql\cluster-data; then, on the computer where you downloaded and extracted the no-install archive, locate ndbd.exe in the C:\mysql\bin directory. Copy this file to the C:\mysql\bin directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the --ndb-connectstring or -c option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=198.51.100.10  # location of management server
```

Save this file as C:\mysql\my.ini on the data node host. Create another text file containing the same information and save it on as C:\mysql\my.ini on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node’s C:\mysql directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

Management node. The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program ndb_mgmd.exe. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program ndb_mgm.exe on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the no-install archive;
Installing NDB Cluster on Windows

this should be the directory C:\mysql\bin on the SQL node host. Create the directory C:\mysql\bin on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by ndb_mgmd.exe:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

To create this file, start a new text file in Notepad or another text editor, and enter the following information:

```
[mysql_cluster]
# Options for management node process
config-file=C:/mysql/bin/config.ini
```

Save this file as the text file C:\mysql\bin\my.ini.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (HostName configuration parameter). It is also advisable to include the following additional information:

- The IP address or hostname of any SQL nodes
- The data memory and index memory allocated to each data node (DataMemory and IndexMemory configuration parameters)
- The number of fragment replicas, using the NoOfReplicas configuration parameter (see Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”)
- The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the DataDir configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2                      # Number of fragment replicas
DataDir=C:/mysql/cluster-data       # Directory for each data node's data files
# Forward slashes used in directory path,
# rather than backslashes. This is correct;
# see Important note in text
DataMemory=80M    # Memory allocated to data storage
IndexMemory=18M   # Memory allocated to index storage
# For DataMemory and IndexMemory, we have used the 
# default values. Since the "world" database takes up
# only about 500KB, this should be more than enough for
# this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10              # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs   # Directory for management node log files

[ndbd]
# Options for data node "A":
HostName=198.51.100.30          # (one [ndbd] section per data node)

[ndbd]
# Options for data node "B":
HostName=198.51.100.40          # Hostname or IP address

[mysqld]
# SQL node options:
```
Installing NDB Cluster on Windows

HostName=198.51.100.20          # Hostname or IP address

Save this file as the text file C:\mysql\bin\config.ini.

**Important**

A single backslash character (\) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\\), or replace the backslash with a forward slash character (/). For example, the following line from the [ndb_mgmd] section of an NDB Cluster config.ini file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
DataDir=C:/mysql/bin/cluster-logs     # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

25.3.2.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- MySQL NDB Cluster 8.4 is built from the MySQL Server 8.4 sources, available from the MySQL downloads page at https://dev.mysql.com/downloads/. The archived source file should have a name similar to `mysql-8.4.0.tar.gz`. You can also obtain the sources from GitHub at https://github.com/mysql/mysql-server.

- You must configure the build using the `WITH_NDB` option in addition to any other build options you wish to use with `CMake`. `WITH_NDBCLUSTER` is also supported for backwards compatibility, but is deprecated and subject to future removal.

**Important**

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. (Bug #12379735) Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see `CMake Options for Compiling NDB Cluster`.

Once the build process is complete, you can create a Zip archive containing the compiled binaries; `Section 2.8.4, “Installing MySQL Using a Standard Source Distribution”` provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see `Section 25.3.2.1, “Installing NDB Cluster on Windows from a Binary Release”`.

25.3.2.3 Initial Startup of NDB Cluster on Windows
Installing NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

   C:\mysql\bin> ndb_mgmd
   2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-8.4.0-ndb-8.4.0
   2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'

   The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which ndb_mgmd.exe is running; doing so kills the management node process. (See Section 25.3.2.4, “Installing NDB Cluster Processes as Windows Services”, where we show how to install and run NDB Cluster processes as Windows services.)

   The required -f option tells the management node where to find the global configuration file (config.ini). The long form of this option is --config-file.

   ! Important

   An NDB Cluster management node caches the configuration data that it reads from config.ini; once it has created a configuration cache, it ignores the config.ini file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read config.ini after you have corrected any errors in it. You can do this by starting ndb_mgmd.exe with the --reload or --initial option on the command line. Either of these options works to refresh the configuration cache.

   It is not necessary or advisable to use either of these options in the management node's my.ini file.

2. On each of the data node hosts, run the command shown here to start the data node processes:

   C:\mysql\bin> ndbd

   In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills ndbd.exe. (For more information, see Section 25.3.2.4, “Installing NDB Cluster Processes as Windows Services”.)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client ndb_mgm.exe, which should be in C:\mysql\bin on the management node host. (Do not try to re-use the console window where ndb_mgmd.exe is running by typing CTRL+C, as this kills the management node.) The resulting output should look like this:

   C:\mysql\bin> ndb_mgm
   -- NDB Cluster -- Management Client --
Installing NDB Cluster on Windows

**ndb_mgm>**

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes’s startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186 (using cleartext)
Node 2: starting (Last completed phase 3) (mysql-8.4.0-ndb-8.4.0)
Node 3: starting (Last completed phase 3) (mysql-8.4.0-ndb-8.4.0)
Node 2: starting (Last completed phase 4) (mysql-8.4.0-ndb-8.4.0)
Node 3: starting (Last completed phase 4) (mysql-8.4.0-ndb-8.4.0)
Node 2: Started (version 8.4.0)
Node 3: Started (version 8.4.0)
```

**Note**

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see Section 25.6.1, “Commands in the NDB Cluster Management Client”.

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186 (using cleartext)
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=2  @198.51.100.30 (Version: 8.4.0-ndb-8.4.0, Nodegroup: 0, *)
id=3  @198.51.100.40 (Version: 8.4.0-ndb-8.4.0, Nodegroup: 0)
[ndb_mgmd(MGM)] 1 node(s)
id=1  @198.51.100.10 (Version: 8.4.0-ndb-8.4.0)
```
You can also verify that the SQL node is connected to the NDB Cluster in the *mysql* client
(*mysql.exe*) using the **SHOW ENGINE NDB STATUS** statement.

You should now be ready to work with database objects and data using NDB Cluster 's **NDBCLUSTER**
storage engine. See Section 25.3.5, "NDB Cluster Example with Tables and Data", for more
information and examples.

You can also install **ndb_mgmd.exe**, **ndbd.exe**, and **ndbmd.exe** as Windows services. For
information on how to do this, see Section 25.3.2.4, "Installing NDB Cluster Processes as Windows
Services".

### 25.3.2.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes
and data nodes as Windows services, so that these processes are started and stopped automatically
whenever Windows is started or stopped. This also makes it possible to control these processes from
the command line with the appropriate **SC START** and **SC STOP** commands, or using the Windows
graphical **Services** utility. **NET START** and **NET STOP** commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator
rights on the system.

To install the management node as a service on Windows, invoke **ndb_mgmd.exe** from the command
line on the machine hosting the management node, using the **--install** option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
   as "C:\mysql\bin\ndbd.exe" --service=ndb_mgmd"
Service successfully installed.
```

#### Important

When installing an NDB Cluster program as a Windows service, you should
always specify the complete path; otherwise the service installation may fail with the error **The system cannot find the file specified**.

The **--install** option must be used first, ahead of any other options that might be specified for
**ndb_mgmd.exe**. However, it is preferable to specify such options in an options file instead. If your
options file is not in one of the default locations as shown in the output of **ndb_mgmd.exe --help**, you
can specify the location using the **--config-file** option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd
C:\> SC STOP ndb_mgmd
```

#### Note

If using **NET** commands, you can also start or stop the management server as a
Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.
C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

It is usually simpler to specify a short service name or to permit the default service name to be used
when installing the service, and then reference that name when starting or stopping the service. To
specify a service name other than \texttt{ndb\_mgmd}, append it to the \texttt{--install} option, as shown in this example:

```
C:\> C:\mysql\bin\ndb\_mgmd\exe --install=mgmd1
Installing service 'NDB Cluster Management Server'
    as "C:\mysql\bin\ndb\_mgmd\exe "--service=mgmd1"
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> SC START mgmd1
C:\> SC STOP mgmd1
```

To remove the management node service, use \texttt{SC DELETE service\_name}:

```
C:\> SC DELETE mgmd1
```

Alternatively, invoke \texttt{ndb\_mgmd\exe} with the \texttt{--remove} option, as shown here:

```
C:\> C:\mysql\bin\ndb\_mgmd\exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, pass the service name as the value of the \texttt{ndb\_mgmd\exe --remove} option, like this:

```
C:\> C:\mysql\bin\ndb\_mgmd\exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.
```

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the \texttt{--install} option for \texttt{ndbd\exe} (or \texttt{ndbmtd\exe}), as shown here:

```
C:\> C:\mysql\bin\ndbd\exe --install
Installing service 'NDB Cluster Data Node Daemon' as "C:\mysql\bin\ndbd\exe "--service=ndbd"
Service successfully installed.
```

Now you can start or stop the data node as shown in the following example:

```
C:\> SC START ndbd
C:\> SC STOP ndbd
```

To remove the data node service, use \texttt{SC DELETE service\_name}:

```
C:\> SC DELETE ndbd
```

Alternatively, invoke \texttt{ndbd\exe} with the \texttt{--remove} option, as shown here:

```
C:\> C:\mysql\bin\ndbd\exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.
```

As with \texttt{ndb\_mgmd\exe} (and \texttt{mysqld\exe}), when installing \texttt{ndbd\exe} as a Windows service, you can also specify a name for the service as the value of \texttt{--install}, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd\exe --install=dnode1
Installing service 'dnode1' as "C:\mysql\bin\ndbd\exe "--service=dnode1"
Service successfully installed.
C:\> SC START dnode1
C:\> SC STOP dnode1
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, as shown here:
25.3.3 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

For our four-node, four-host NDB Cluster (see Cluster nodes and host computers), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a my.cnf file that provides two pieces of information: a connection string that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the NDBCLUSTER storage engine.

  For more information on connection strings, see Section 25.4.3.3, “NDB Cluster Connection Strings”.

- The management node needs a config.ini file telling it how many fragment replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the data nodes and SQL nodes. The my.cnf file needed for the data nodes is fairly simple. The configuration file should be located in the /etc directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```bash
$> vi /etc/my.cnf
```

Note

We show vi being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, my.cnf should look like this:

```ini
[mysqld]
# Options for mysqld process:
ndbcluster # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
ndb-connectstring=198.51.100.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

Important

Once you have started a mysqld process with the ndbcluster and ndb-connectstring parameters in the [mysqld] and [mysql_cluster] sections of the my.cnf file as shown previously, you cannot execute any CREATE TABLE or ALTER TABLE statements without having actually started the cluster. Otherwise, these statements fail with an error. This is by design.
Configuring the management node. The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as root):

```bash
$> mkdir /var/lib/mysql-cluster
$> cd /var/lib/mysql-cluster
$> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of fragment replicas
DataMemory=98M    # How much memory to allocate for data storage

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10          # Hostname or IP address of management node
DataDir=/var/lib/mysql-cluster  # Directory for management node log files

[ndbd]
# Options for data node "A":
HostName=198.51.100.30          # Hostname or IP address
NodeId=2                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files

[ndbd]
# Options for data node "B":
HostName=198.51.100.40          # Hostname or IP address
NodeId=3                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files

[mysqld]
# SQL node options:
HostName=198.51.100.20          # Hostname or IP address
# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)
```

Note

The `world` database can be downloaded from [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html).

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 25.3.4, “Initial Startup of NDB Cluster”.

For more detailed information about the available NDB Cluster configuration parameters and their uses, see Section 25.4.3, “NDB Cluster Configuration Files”, and Section 25.4, “Configuration of NDB Cluster”. For configuration of NDB Cluster as relates to making backups, see Section 25.6.8.3, “Configuration for NDB Cluster Backups”.

Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

25.3.4 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:
1. On the management host, issue the following command from the system shell to start the management node process:

   ```
   $> ndb_mgmd --initial -f /var/lib/mysql-cluster/config.ini
   ```

   The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. This option requires that `--initial` or `--reload` also be specified; see Section 25.5.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, for details.

2. On each of the data node hosts, run this command to start the `ndbd` process:

   ```
   $> ndbd
   ```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

   If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

   ```
   $> ndb_mgm
   -- NDB Cluster -- Management Client --
   ndb_mgm> SHOW
   Connected to Management Server at: localhost:1186 (using cleartext)
   Cluster Configuration
   ---------------------
   [ndbd(NDB)]     2 node(s)
   id=2    @198.51.100.30  (Version: 8.4.0-ndb-8.4.0, Nodegroup: 0, *)
   id=3    @198.51.100.40  (Version: 8.4.0-ndb-8.4.0, Nodegroup: 0)
   [ndb_mgmd(MGM)] 1 node(s)
   id=1    @198.51.100.10  (Version: 8.4.0-ndb-8.4.0)
   [mysqld(API)]   1 node(s)
   id=4    @198.51.100.20  (Version: 8.4.0-ndb-8.4.0)
   ```

   The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as an NDB Cluster API node.

   **Note**

   The IP address shown for a given NDB Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

   You should now be ready to work with databases, tables, and data in NDB Cluster. See Section 25.3.5, “NDB Cluster Example with Tables and Data”, for a brief discussion.

### 25.3.5 NDB Cluster Example with Tables and Data

**Note**

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

  ```
  CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
  ```
Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support NDB Cluster, and you want to export the `City` table:

```
$> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file contains this table creation statement (and the `INSERT` statements necessary to import the table data):

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=MyISAM;
```

```
INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition before importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=NDBCLUSTER;
```

```
INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
$> mysql world < city_table.sql
```

3833
It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address \texttt{198.51.100.20}).

To create a copy of the entire \texttt{world} database on the SQL node, use \texttt{mysqldump} on the noncluster server to export the database to a file named \texttt{world.sql} (for example, in the \texttt{/tmp} directory). Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

\begin{verbatim}
$> mysql world < /tmp/world.sql
\end{verbatim}

If you save the file to a different location, adjust the preceding instructions accordingly.

Running \texttt{SELECT} queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the root password at the Enter password: prompt):

\begin{verbatim}
$> mysql -u root -p
Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.4.0-ndb-8.4.0
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
\end{verbatim}

We simply use the MySQL server's root account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong root password. For more information, see Section 2.9.4, “Securing the Initial MySQL Account”.

It is worth taking into account that NDB Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the root account) effects only applications that access the SQL node, not interaction between nodes. See Section 25.6.21.2, “NDB Cluster and MySQL Privileges”, for more information.

If you did not modify the \texttt{ENGINE} clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

\begin{verbatim}
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
\end{verbatim}

Selecting a database and running a \texttt{SELECT} query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

\begin{verbatim}
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bombay</td>
<td>10500000</td>
</tr>
<tr>
<td>Seoul</td>
<td>9981619</td>
</tr>
<tr>
<td>São Paulo</td>
<td>9968485</td>
</tr>
<tr>
<td>Shanghai</td>
<td>9696300</td>
</tr>
<tr>
<td>Jakarta</td>
<td>9604900</td>
</tr>
</tbody>
</table>
+-----------+------------+
5 rows in set (0.34 sec)
mysql> \q
Bye
$>
\end{verbatim}

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the \texttt{SELECT} statement just shown by using the PHP 5.X \texttt{mysqli} extension running on a Web server elsewhere on the network:
We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

### 25.3.6 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```bash
$> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtd` processes to terminate gracefully.
Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `SC STOP service_name` or `NET STOP service_name`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (`198.51.100.10` in our example setup):
  
  ```
  $> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- On each of the data node hosts (`198.51.100.30` and `198.51.100.40`):
  
  ```
  $> ndbd
  ```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (`198.51.100.20`):
  
  ```
  $> mysqld_safe &
  ```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see Section 25.3.2.4, “Installing NDB Cluster Processes as Windows Services”), you can restart the cluster as follows:

- On the management host (`198.51.100.10` in our example setup), execute the following command:
  
  ```
  C:\> SC START ndb_mgmd
  ```

- On each of the data node hosts (`198.51.100.30` and `198.51.100.40`), execute the following command:
  
  ```
  C:\> SC START ndbd
  ```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see Section 25.3.2.3, “Initial Startup of NDB Cluster on Windows”).

- On the SQL node host (`198.51.100.20`), execute the following command:
  
  ```
  C:\> SC START mysql
  ```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”.

### 25.3.7 Upgrading and Downgrading NDB Cluster

- **Versions Supported for Upgrade to NDB 8.4**

- **Known Issues When Upgrading or Downgrading NDB Cluster**

This section provides information about NDB Cluster software and compatibility between different NDB Cluster releases with regard to performing upgrades and downgrades. You should already be familiar with installing and configuring NDB Cluster prior to attempting an upgrade or downgrade. See Section 25.4, “Configuration of NDB Cluster”.

For information about upgrades to NDB 8.4 from previous versions, see **Versions Supported for Upgrade to NDB 8.4**.

For information about known issues and problems encountered when upgrading or downgrading NDB 8.4, see **Known Issues When Upgrading or Downgrading NDB Cluster**.
Versions Supported for Upgrade to NDB 8.4

The following versions of NDB Cluster are supported for upgrades to NDB Cluster 8.4:

- NDB Cluster 8.0: NDB 8.0.19 and later
- NDB Cluster 8.1 (8.1.0)
- NDB Cluster 8.2 (8.2.0)
- NDB Cluster 8.3 (8.3.0)

Known Issues When Upgrading or Downgrading NDB Cluster

In this section, provide information about issues known to occur when upgrading or downgrading to or from NDB 8.4.

We recommend that you not attempt any schema changes during any NDB Cluster software upgrade or downgrade. Some of the reasons for this are listed here:

- DDL statements on NDB tables are not possible during some phases of data node startup.
- DDL statements on NDB tables may be rejected if any data nodes are stopped during execution; stopping each data node binary (so it can be replaced with a binary from the target version) is required as part of the upgrade or downgrade process.
- DDL statements on NDB tables are not allowed while there are data nodes in the same cluster running different release versions of the NDB Cluster software.

For additional information regarding the rolling restart procedure used to perform an online upgrade or downgrade of the data nodes, see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”.

25.4 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the NDB storage engine. This engine is also referred to sometimes as NDBCLUSTER, although NDB is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the NDB storage engine disabled. To enable NDB, you must modify the server's my.cnf configuration file, or start the server with the --ndbcluster option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on localhost. However, should you need to specify that its location is elsewhere, this can be done in my.cnf, or with the mysql client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about --ndbcluster and other mysqld options specific to NDB Cluster, see MySQL Server Options for NDB Cluster.

For general information about installing NDB Cluster, see Section 25.3, “NDB Cluster Installation”.

25.4.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as /var/lib/mysql-cluster, by executing the following command as the system root user:

```
$> mkdir /var/lib/mysql-cluster
```
In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```ini
# file "config.ini" - showing minimal setup consisting of 1 data node, 
# 1 management server, and 3 MySQL servers. 
# The empty default sections are not required, and are shown only for 
# the sake of completeness. 
# Data nodes must provide a hostname but MySQL Servers are not required 
# to do so. 
# If you do not know the hostname for your machine, use localhost. 
# The DataDir parameter also has a default value, but it is recommended to 
# set it explicitly. 
# [api] and [mgm] are aliases for [mysqld] and [ndb_mgmd], respectively.

[ndbd default]
NoOfReplicas= 1

[mysqld  default]

[ndb_mgmd default]
[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
$> cd /var/lib/mysql-cluster
$> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
$> ndbd
```

By default, `ndbd` looks for the management server at `localhost` on port 1186.

**Note**

If you have installed MySQL from a binary tarball, you must specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these can be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
$> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:
Overview of NDB Cluster Configuration Parameters, Options, and Variables

Try to create an `NDBCLUSTER` table:

```sql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```bash
$> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 8.4.0-ndb-8.4.0, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 8.4.0-ndb-8.4.0)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 8.4.0-ndb-8.4.0)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

**25.4.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables**

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

read by mysqld from a my.cnf file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (ndbd, ndb_mgmd, mysqld, computer, tcp, or shm). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

Considerations when restarting nodes. For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with --initial—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a rolling restart). It is possible to update cluster configuration parameters marked as node online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each ndbd process with the --initial option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

Note

4294967039 often appears as a maximum value in these tables. This value is defined in the NDBCLUSTER sources as MAX_INT_RNIL and is equal to 0xFFFFFEFF, or $2^{32} - 2^8 - 1$.

25.4.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the [ndbd] or [ndbd default] sections of a config.ini file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 25.4.3.6, “Defining NDB Cluster Data Nodes”.

These parameters also apply to ndbmtd, the multithreaded version of ndbd. A separate listing of parameters specific to ndbmtd follows.

• **Arbitration**: How arbitration should be performed to avoid split-brain issues in event of node failure.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ArbitrationTimeout**: Maximum time (milliseconds) database partition waits for arbitration signal.
- **BackupDataBufferSize**: Default size of databuffer for backup (in bytes).
- **BackupDataDir**: Path to where to store backups. Note that string '/BACKUP' is always appended to this setting, so that "effective" default is FileSystemPath/BACKUP.
- **BackupDiskWriteSpeedPct**: Sets percentage of data node's allocated maximum write speed (MaxDiskWriteSpeed) to reserve for LCPs when starting backup.
- **BackupLogBufferSize**: Default size of log buffer for backup (in bytes).
- **BackupMaxWriteSize**: Maximum size of file system writes made by backup (in bytes).
- **BackupMemory**: Total memory allocated for backups per node (in bytes).
- **BackupReportFrequency**: Frequency of backup status reports during backup in seconds.
- **BackupWriteSize**: Default size of file system writes made by backup (in bytes).
- **BatchSizePerLocalScan**: Used to calculate number of lock records for scan with hold lock.
- **BuildIndexThreads**: Number of threads to use for building ordered indexes during system or node restart. Also applies when running ndb_restore --rebuild-indexes. Setting this parameter to 0 disables multithreaded building of ordered indexes.
- **CompressedBackup**: Use zlib to compress backups as they are written.
- **CompressedLCP**: Write compressed LCPs using zlib.
- **ConnectCheckIntervalDelay**: Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.
- **CrashOnCorruptedTuple**: When enabled, forces node to shut down whenever it detects corrupted tuple.
- **DataDir**: Data directory for this node.
- **DataMemory**: Number of bytes on each data node allocated for storing data; subject to available system RAM and size of IndexMemory.
- **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.
- **DictTrace**: Enable DBDICT debugging; for NDB development.
- **DiskDataUsingSameDisk**: Set to false if Disk Data tablespaces are located on separate physical disks.
- **DiskIOThreadPool**: Number of unbound threads for file access, applies to disk data only.
- **Diskless**: Run without using disk.
- **DiskPageBufferEntries**: Memory to allocate in DiskPageBufferMemory; very large disk transactions may require increasing this value.
- **DiskPageBufferMemory**: Number of bytes on each data node allocated for disk page buffer cache.
- **DiskSyncSize**: Amount of data written to file before synch is forced.
- **EnablePartialLcp**: Enable partial LCP (true); if this is disabled (false), all LCPs write full checkpoints.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **EnableRedoControl**: Enable adaptive checkpointing speed for controlling redo log usage.
- **EncryptedFileSystem**: Encrypt local checkpoint and tablespace files. EXPERIMENTAL; NOT SUPPORTED IN PRODUCTION.
- **EventLogBufferSize**: Size of circular buffer for NDB log events within data nodes.
- **ExecuteOnComputer**: String referencing earlier defined COMPUTER.
- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- **FileSystemPath**: Path to directory where data node stores its data (directory must exist).
- **FileSystemPathDataFiles**: Path to directory where data node stores its Disk Data files. Default value is FileSystemPathDD, if set; otherwise, FileSystemPath is used if it is set; otherwise, value of DataDir is used.
- **FileSystemPathDD**: Path to directory where data node stores its Disk Data and undo files. Default value is FileSystemPath, if set; otherwise, value of DataDir is used.
- **FileSystemPathUndoFiles**: Path to directory where data node stores its undo files for Disk Data. Default value is FileSystemPathDD, if set; otherwise, FileSystemPath is used if it is set; otherwise, value of DataDir is used.
- **FragmentLogFileSize**: Size of each redo log file.
- **HeartbeatIntervalDbApi**: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats).
- **HeartbeatIntervalDbDb**: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats.
- **HeartbeatOrder**: Sets order in which data nodes check each others' heartbeats for determining whether given node is still active and connected to cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.
- **HostName**: Host name or IP address for this data node.
- **IndexMemory**: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.
- **IndexStatAutoCreate**: Enable/disable automatic statistics collection when indexes are created.
- **IndexStatAutoUpdate**: Monitor indexes for changes and trigger automatic statistics updates.
- **IndexStatSaveScale**: Scaling factor used in determining size of stored index statistics.
- **IndexStatSaveSize**: Maximum size in bytes for saved statistics per index.
- **IndexStatTriggerPct**: Threshold percent change in DML operations for index statistics updates. Value is scaled down by IndexStatTriggerScale.
- **IndexStatTriggerScale**: Scale down IndexStatTriggerPct by this amount, multiplied by base 2 logarithm of index size, for large index. Set to 0 to disable scaling.
- **IndexStatUpdateDelay**: Minimum delay between automatic index statistics updates for given index. 0 means no delay.
- **InitFragmentLogFiles**: Initialize fragment log files, using sparse or full format.
- **InitialLogFileGroup**: Describes log file group that is created during initial start. See documentation for format.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **InitialNoOfOpenFiles**: Initial number of files open per data node. (One thread is created per file).
- **InitialTablespace**: Describes tablespace that is created during initial start. See documentation for format.
- **InsertRecoveryWork**: Percentage of RecoveryWork used for inserted rows; has no effect unless partial local checkpoints are in use.
- **KeepAliveSendInterval**: Time between keep-alive signals on links between data nodes, in milliseconds. Set to 0 to disable.
- **LateAlloc**: Allocate memory after connection to management server has been established.
- **LcpScanProgressTimeout**: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.
- **LocationDomainId**: Assign this data node to specific availability domain or zone. 0 (default) leaves this unset.
- **LockExecuteThreadToCPU**: Comma-delimited list of CPU IDs.
- **LockMaintThreadsToCPU**: CPU ID indicating which CPU runs maintenance threads.
- **LockPagesInMainMemory**: 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation.
- **LogLevelCheckpoint**: Log level of local and global checkpoint information printed to stdout.
- **LogLevelCongestion**: Level of congestion information printed to stdout.
- **LogLevelConnection**: Level of node connect/disconnect information printed to stdout.
- **LogLevelError**: Transporter, heartbeat errors printed to stdout.
- **LogLevelInfo**: Heartbeat and log information printed to stdout.
- **LogLevelNodeRestart**: Level of node restart and node failure information printed to stdout.
- **LogLevelShutdown**: Level of node shutdown information printed to stdout.
- **LogLevelStartup**: Level of node startup information printed to stdout.
- **LogLevelStatistic**: Level of transaction, operation, and transporter information printed to stdout.
- **LongMessageBuffer**: Number of bytes allocated on each data node for internal long messages.
- **MaxAllocate**: No longer used; has no effect.
- **MaxBufferedEpochs**: Allowed number of epochs that subscribing node can lag behind (unprocessed epochs). Exceeding causes lagging subscribers to be disconnected.
- **MaxBufferedEpochBytes**: Total number of bytes allocated for buffering epochs.
- **MaxDiskDataLatency**: Maximum allowed mean latency of disk access (ms) before starting to abort transactions.
- **MaxDiskWriteSpeed**: Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.
- **MaxDiskWriteSpeedOtherNodeRestart**: Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.
- **MaxDiskWriteSpeedOwnRestart**: Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **MaxFKBuildBatchSize**: Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well.

- **MaxDMLOperationsPerTransaction**: Limit size of transaction; aborts transaction if it requires more than this many DML operations.

- **MaxLCPStartDelay**: Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.

- **MaxNoOfAttributes**: Suggests total number of attributes stored in database (sum over all tables).

- **MaxNoOfConcurrentIndexOperations**: Total number of index operations that can execute simultaneously on one data node.

- **MaxNoOfConcurrentOperations**: Maximum number of operation records in transaction coordinator.

- **MaxNoOfConcurrentScans**: Maximum number of scans executing concurrently on data node.

- **MaxNoOfConcurrentSubOperations**: Maximum number of concurrent subscriber operations.

- **MaxNoOfConcurrentTransactions**: Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster.

- **MaxNoOfFiredTriggers**: Total number of triggers that can fire simultaneously on one data node.

- **MaxNoOfLocalOperations**: Maximum number of operation records defined on this data node.

- **MaxNoOfLocalScans**: Maximum number of fragment scans in parallel on this data node.

- **MaxNoOfOpenFiles**: Maximum number of files open per data node. (One thread is created per file).

- **MaxNoOfOrderedIndexes**: Total number of ordered indexes that can be defined in system.

- **MaxNoOfSavedMessages**: Maximum number of error messages to write in error log and maximum number of trace files to retain.

- **MaxNoOfSubscribers**: Maximum number of subscribers.

- **MaxNoOfSubscriptions**: Maximum number of subscriptions (default 0 = MaxNoOfTables).

- **MaxNoOfTables**: Suggests total number of NDB tables stored in database.

- **MaxNoOfTriggers**: Total number of triggers that can be defined in system.

- **MaxNoOfUniqueHashIndexes**: Total number of unique hash indexes that can be defined in system.

- **MaxParallelCopyInstances**: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to maximum of 16.

- **MaxParallelScansPerFragment**: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.

- **MaxReorgBuildBatchSize**: Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well.

- **MaxStartFailRetries**: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.

- **MaxUIBuildBatchSize**: Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **MemReportFrequency**: Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits.
- **MinDiskWriteSpeed**: Minimum number of bytes per second that can be written by LCP and backup.
- **MinFreePct**: Percentage of memory resources to keep in reserve for restarts.
- **NodeGroup**: Node group to which data node belongs; used only during initial start of cluster.
- **NodeGroupTransporters**: Number of transporters to use between nodes in same node group.
- **NodeId**: Number uniquely identifying data node among all nodes in cluster.
- **NoOfFragmentLogFiles**: Number of 16 MB redo log files in each of 4 file sets belonging to data node.
- **NoOfReplicas**: Number of copies of all data in database.
- **Numa**: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- **ODirect**: Use O_DIRECT file reads and writes when possible.
- **ODirectSyncFlag**: O_DIRECT writes are treated as synchronized writes; ignored when ODirect is not enabled, InitFragmentLogFiles is set to SPARSE, or both.
- **RealtimeScheduler**: When true, data node threads are scheduled as real-time threads. Default is false.
- **RecoveryWork**: Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery.
- **RedoBuffer**: Number of bytes on each data node allocated for writing redo logs.
- **RedoOverCommitCounter**: When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.
- **RedoOverCommitLimit**: Each time that flushing current redo buffer takes longer than this many seconds, number of times that this has happened is compared to RedoOverCommitCounter.
- **RequireEncryptedBackup**: Whether backups must be encrypted (1 = encryption required, otherwise 0).
- **RequireCertificate**: Node is required to find key and certificate in TLS search path.
- **RequireTls**: Require TLS-authenticated secure connections.
- **ReservedConcurrentIndexOperations**: Number of simultaneous index operations having dedicated resources on one data node.
- **ReservedConcurrentOperations**: Number of simultaneous operations having dedicated resources in transaction coordinators on one data node.
- **ReservedConcurrentScans**: Number of simultaneous scans having dedicated resources on one data node.
- **ReservedConcurrentTransactions**: Number of simultaneous transactions having dedicated resources on one data node.
- **ReservedFiredTriggers**: Number of triggers having dedicated resources on one data node.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ReservedLocalScans**: Number of simultaneous fragment scans having dedicated resources on one data node.
- **ReservedTransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.
- **RestartOnErrorInsert**: Control type of restart caused by inserting error (when StopOnError is enabled).
- **RestartSubscriberConnectTimeout**: Amount of time for data node to wait for subscribing API nodes to connect. Set to 0 to disable timeout, which is always resolved to nearest full second.
- **SchedulerExecutionTimer**: Number of microseconds to execute in scheduler before sending.
- **SchedulerResponsiveness**: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput.
- **SchedulerSpinTimer**: Number of microseconds to execute in scheduler before sleeping.
- **ServerPort**: Port used to set up transporter for incoming connections from API nodes.
- **SharedGlobalMemory**: Total number of bytes on each data node allocated for any use.
- **SpinMethod**: Determines spin method used by data node; see documentation for details.
- **StartFailRetryDelay**: Delay in seconds after start failure prior to retry; requires StopOnError = 0.
- **StartFailureTimeout**: Milliseconds to wait before terminating. (0=Wait forever).
- **StartNoNodeGroupTimeout**: Time to wait for nodes without nodegroup before trying to start (0=forever).
- **StartPartialTimeout**: Milliseconds to wait before trying to start without all nodes. (0=Wait forever).
- **StartPartitionedTimeout**: Milliseconds to wait before trying to start partitioned. (0=Wait forever).
- **StartupStatusReportFrequency**: Frequency of status reports during startup.
- **StopOnError**: When set to 0, data node automatically restarts and recovers following node failures.
- **StringMemory**: Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes).
- **TcpBind_INADDR_ANY**: Bind IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections).
- **TimeBetweenEpochs**: Time between epochs (synchronization used for replication).
- **TimeBetweenEpochsTimeout**: Timeout for time between epochs. Exceeding causes node shutdown.
- **TimeBetweenGlobalCheckpoints**: Time between group commits of transactions to disk.
- **TimeBetweenGlobalCheckpointsTimeout**: Minimum timeout for group commit of transactions to disk.
- **TimeBetweenInactiveTransactionAbortCheck**: Time between checks for inactive transactions.
- **TimeBetweenLocalCheckpoints**: Time between taking snapshots of database (expressed in base-2 logarithm of bytes).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **TimeBetweenWatchDogCheck**: Time between execution checks inside data node.
- **TimeBetweenWatchDogCheckInitial**: Time between execution checks inside data node (early start phases when memory is allocated).
- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.
- **TransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated for each data node.
- **TransactionDeadlockDetectionTimeout**: Time transaction can spend executing within data node. This is time that transaction coordinator waits for each data node participating in transaction to execute request. If data node takes more than this amount of time, transaction is aborted.
- **TransactionInactiveTimeout**: Milliseconds that application waits before executing another part of transaction. This is time transaction coordinator waits for application to execute or send another part (query, statement) of transaction. If application takes too much time, then transaction is aborted. Timeout = 0 means that application never times out.
- **TransactionMemory**: Memory allocated for transactions on each data node.
- **TwoPassInitialNodeRestartCopy**: Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.
- **UndoDataBuffer**: Unused; has no effect.
- **UndoIndexBuffer**: Unused; has no effect.
- **UseShm**: Use shared memory connections between this data node and API node also running on this host.
- **WatchDogImmediateKill**: When true, threads are immediately killed whenever watchdog issues occur; used for testing and debugging.

The following parameters are specific to **ndbmd**:

- **AutomaticThreadConfig**: Use automatic thread configuration; overrides any settings for ThreadConfig and MaxNoOfExecutionThreads, and disables ClassicFragmentation.
- **ClassicFragmentation**: When true, use traditional table fragmentation; set false to enable flexible distribution of fragments among LDMs. Disabled by AutomaticThreadConfig.
- **EnableMultithreadedBackup**: Enable multi-threaded backup.
- **MaxNoOfExecutionThreads**: For ndbmd only, specify maximum number of execution threads.
- **MaxSendDelay**: Maximum number of microseconds to delay sending by ndbmd.
- **NoOfFragmentLogParts**: Number of redo log file groups belonging to this data node.
- **NumCPUs**: Specify number of CPUs to use with AutomaticThreadConfig.
- **PartitionsPerNode**: Determines the number of table partitions created on each data node; not used if ClassicFragmentation is enabled.
- **ThreadConfig**: Used for configuration of multithreaded data nodes (ndbmd). Default is empty string; see documentation for syntax and other information.

**25.4.2.2 NDB Cluster Management Node Configuration Parameters**

The listing in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` section of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 25.4.3.5, "Defining an NDB Cluster Management Server".
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this long before voting (milliseconds).

- **ArbitrationRank**: If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2.

- **DataDir**: Data directory for this node.

- **ExecuteOnComputer**: String referencing earlier defined COMPUTER.

- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- **HeartbeatIntervalMgmdMgmd**: Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats.

- **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for management nodes; see manual for allowed values.

- **HostName**: Host name or IP address for this management node.

- **Id**: Number identifying management node. Now deprecated; use NodeId instead.

- **LocationDomainId**: Assign this management node to specific availability domain or zone. 0 (default) leaves this unset.

- **LogDestination**: Where to send log messages: console, system log, or specified log file.

- **NodeId**: Number uniquely identifying management node among all nodes in cluster.

- **PortNumber**: Port number to send commands to and fetch configuration from management server.

- **PortNumberStats**: Port number used to get statistical information from management server.

- **RequireTls**: Client connection must authenticate with TLS before being used otherwise.

- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.

- **wan**: Use WAN TCP setting as default.

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 25.4.3.5, “Defining an NDB Cluster Management Server”, for more information.

To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing config.ini files. For more information about issues arising when using multiple management nodes, see Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### 25.4.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the [mysqld] and [api] sections of a config.ini file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **ApiVerbose**: Enable NDB API debugging; for NDB development.

- **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this many milliseconds before voting.

- **ArbitrationRank**: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **AutoReconnect**: Specifies whether an API node should reconnect fully when disconnected from cluster.

- **BatchByteSize**: Default batch size in bytes.

- **BatchSize**: Default batch size in number of records.

- **ConnectBackoffMaxTime**: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead.

- **ConnectionMap**: Specifies which data nodes to connect.

- **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.

- **DefaultOperationRedoProblemAction**: How operations are handled in event that RedoOverCommitCounter is exceeded.

- **ExecuteOnComputer**: String referencing earlier defined COMPUTER.

- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for API nodes; see manual for allowed values.

- **HostName**: Host name or IP address for this SQL or API node.

- **Id**: Number identifying MySQL server or API node (Id). Now deprecated; use NodeId instead.

- **LocationDomainId**: Assign this API node to specific availability domain or zone. 0 (default) leaves this unset.

- **MaxScanBatchSize**: Maximum collective batch size for one scan.

- **NodeId**: Number uniquely identifying SQL node or API node among all nodes in cluster.

- **StartConnectBackoffMaxTime**: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node.

- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.

- **wan**: Use WAN TCP setting as default.

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster. For information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.
25.4.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the [computer], [tcp], and [shm] sections of a config.ini file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see Section 25.4.3.10, “NDB Cluster TCP/IP Connections”, or Section 25.4.3.12, “NDB Cluster Shared-Memory Connections”, as appropriate.

The following parameters apply to the config.ini file's [computer] section:

• HostName: Host name or IP address of this computer.
• Id: Unique identifier for this computer.

The following parameters apply to the config.ini file's [tcp] section:

• AllowUnresolvedHostNames: When false (default), failure by management node to resolve host name results in fatal error; when true, unresolved host names are reported as warnings only.
• Checksum: If checksum is enabled, all signals between nodes are checked for errors.
• Group: Used for group proximity; smaller value is interpreted as being closer.
• HostName1: Name or IP address of first of two computers joined by TCP connection.
• HostName2: Name or IP address of second of two computers joined by TCP connection.
• NodeId1: ID of node (data node, API node, or management node) on one side of connection.
• NodeId2: ID of node (data node, API node, or management node) on one side of connection.
• NodeIdServer: Set server side of TCP connection.
• OverloadLimit: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
• PreferIPVersion: Indicate DNS resolver preference for IP version 4 or 6.
• PreSendChecksum: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors.
• Proxy: ....
• ReceiveBufferMemory: Bytes of buffer for signals received by this node.
• RequireLinkTls: Read-only; is set to true if either endpoint of this connection requires TLS.
• SendBufferMemory: Bytes of TCP buffer for signals sent from this node.
• SendSignalId: Sends ID in each signal. Used in trace files. Defaults to true in debug builds.
• TcpSpinTime: Time to spin before going to sleep when receiving.
• TCP_MAXSEG_SIZE: Value used for TCP_MAXSEG.
• TCP_RCV_BUF_SIZE: Value used for SO_RCVBUF.
• TCP_SND_BUF_SIZE: Value used for SO_SNDBUF.
• TcpBind_INADDR_ANY: Bind InAddrAny instead of host name for server part of connection.

The following parameters apply to the config.ini file's [shm] section:

• Checksum: If checksum is enabled, all signals between nodes are checked for errors.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Group**: Used for group proximity; smaller value is interpreted as being closer.
- **HostName1**: Name or IP address of first of two computers joined by SHM connection.
- **HostName2**: Name or IP address of second of two computers joined by SHM connection.
- **NodeId1**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeId2**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeIdServer**: Set server side of SHM connection.
- **OverloadLimit**: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- **PreSendChecksum**: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors.
- **SendBufferMemory**: Bytes in shared memory buffer for signals sent from this node.
- **SendSignalId**: Sends ID in each signal. Used in trace files.
- **ShmKey**: Shared memory key; when set to 1, this is calculated by NDB.
- **ShmSpinTime**: When receiving, number of microseconds to spin before sleeping.
- **ShmSize**: Size of shared memory segment.
- **Signum**: Signal number to be used for signalling.

25.4.2.5 NDB Cluster mysqld Option and Variable Reference

The following list includes command-line options, system variables, and status variables applicable within *mysqld* when it is running as an SQL node in an NDB Cluster. For a reference to all command-line options, system variables, and status variables used with or relating to *mysqld*, see Section 7.1.4, “Server Option, System Variable, and Status Variable Reference”.

- **Com show ndb status**: Count of SHOW NDB STATUS statements.
- **Handler discover**: Number of times that tables have been discovered.
- **ndb-applier-allow-skip-epoch**: Lets replication applier skip epochs.
- **ndb-batch-size**: Size (in bytes) to use for NDB transaction batches.
- **ndb-blob-read-batch-bytes**: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- **ndb-blob-write-batch-bytes**: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- **ndb-cluster-connection-pool**: Number of connections to cluster used by MySQL.
- **ndb-cluster-connection-pool-nodeids**: Comma-separated list of node IDs for connections to cluster used by MySQL; number of nodes in list must match value set for --ndb-cluster-connection-pool.
- **ndb-connectstring**: Address of NDB management server distributing configuration information for this cluster.
- **ndb-default-column-format**: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding table columns.
- `ndb-deferred-constraints`: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.

- `ndb-distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).

- `ndb-log-apply-status`: Cause MySQL server acting as replica to log mysql.ndb_apply_status updates received from its immediate source in its own binary log, using its own server ID. Effective only if server is started with --ndbcluster option.

- `ndb-log-empty-epochs`: When enabled, causes epochs in which there were no changes to be written to ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

- `ndb-log-empty-update`: When enabled, causes updates that produced no changes to be written to ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

- `ndb-log-exclusive-reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.

- `ndb-log-fail-terminate`: Terminate mysqld process if complete logging of all found row events is not possible.

- `ndb-log-orig`: Log originating server id and epoch in mysql.ndb_binlog_index table.

- `ndb-log-transaction-dependency`: Make binary log thread calculate transaction dependencies for every transaction it writes to binary log.

- `ndb-log-transaction-id`: Write NDB transaction IDs in binary log. Requires --log-bin-v1-events=OFF.

- `ndb-log-update-minimal`: Log updates in minimal format.

- `ndb-log-updated-only`: Log updates only (ON) or complete rows (OFF).

- `ndb-log-update-as-write`: Toggles logging of updates on source between updates (OFF) and writes (ON).

- `ndb-mgm-tls`: Whether TLS connection requirements are strict or relaxed.

- `ndb-mgmd-host`: Set host (and port, if desired) for connecting to management server.

- `ndb-nodeid`: NDB Cluster node ID for this MySQL server.

- `ndb-tls-search-path`: Directories to search for NDB TLS CAs and private keys.

- `ndb-transid-mysql-connection-map`: Enable or disable ndb_transid_mysql_connection_map plugin; that is, enable or disable INFORMATION_SCHEMA table having that name.

- `ndb-wait-connected`: Time (in seconds) for MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.

- `ndb-wait-setup`: Time (in seconds) for MySQL server to wait for NDB engine setup to complete.

- `ndb-allow-copying-alter-table`: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables.

- `Ndb_api_adaptive_send_deferred_count`: Number of adaptive send calls not actually sent by this MySQL Server (SQL node).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_adaptive_send_deferred_count_session**: Number of adaptive send calls not actually sent in this client session.
- **Ndb_api_adaptive_send_deferred_count_replica**: Number of adaptive send calls not actually sent by this replica.
- **Ndb_api_adaptive_send_deferred_count_slave**: Number of adaptive send calls not actually sent by this replica.
- **Ndb_api_adaptive_send_forced_count**: Number of adaptive sends with forced-send set sent by this MySQL Server (SQL node).
- **Ndb_api_adaptive_send_forced_count_session**: Number of adaptive sends with forced-send set in this client session.
- **Ndb_api_adaptive_send_forced_count_replica**: Number of adaptive sends with forced-send set sent by this replica.
- **Ndb_api_adaptive_send_forced_count_slave**: Number of adaptive sends with forced-send set sent by this replica.
- **Ndb_api_adaptive_send_unforced_count**: Number of adaptive sends without forced-send sent by this MySQL Server (SQL node).
- **Ndb_api_adaptive_send_unforced_count_session**: Number of adaptive sends without forced-send in this client session.
- **Ndb_api_adaptive_send_unforced_count_replica**: Number of adaptive sends without forced-send sent by this replica.
- **Ndb_api_adaptive_send_unforced_count_slave**: Number of adaptive sends without forced-send sent by this replica.
- **Ndb_api_bytes_received_count**: Quantity of data (in bytes) received from data nodes by this MySQL Server (SQL node).
- **Ndb_api_bytes_received_count_session**: Quantity of data (in bytes) received from data nodes in this client session.
- **Ndb_api_bytes_received_count_replica**: Quantity of data (in bytes) received from data nodes by this replica.
- **Ndb_api_bytes_received_count_slave**: Quantity of data (in bytes) received from data nodes by this replica.
- **Ndb_api_bytes_sent_count**: Quantity of data (in bytes) sent to data nodes by this MySQL Server (SQL node).
- **Ndb_api_bytes_sent_count_session**: Quantity of data (in bytes) sent to data nodes in this client session.
- **Ndb_api_bytes_sent_count_replica**: Quantity of data (in bytes) sent to data nodes by this replica.
- **Ndb_api_bytes_sent_count_slave**: Quantity of data (in bytes) sent to data nodes by this replica.
- **Ndb_api_event_bytes_count**: Number of bytes of events received by this MySQL Server (SQL node).
- **Ndb_api_event_bytes_count_injector**: Number of bytes of event data received by NDB binary log injector thread.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_event_data_count**: Number of row change events received by this MySQL Server (SQL node).
- **Ndb_api_event_data_count_injector**: Number of row change events received by NDB binary log injector thread.
- **Ndb_api_event_nondata_count**: Number of events received, other than row change events, by this MySQL Server (SQL node).
- **Ndb_api_event_nondata_count_injector**: Number of events received, other than row change events, by NDB binary log injector thread.
- **Ndb_api_pk_op_count**: Number of operations based on or using primary keys by this MySQL Server (SQL node).
- **Ndb_api_pk_op_count_session**: Number of operations based on or using primary keys in this client session.
- **Ndb_api_pk_op_count_replica**: Number of operations based on or using primary keys by this replica.
- **Ndb_api_pk_op_count_slave**: Number of operations based on or using primary keys by this replica.
- **Ndb_api_pruned_scan_count**: Number of scans that have been pruned to one partition by this MySQL Server (SQL node).
- **Ndb_api_pruned_scan_count_session**: Number of scans that have been pruned to one partition in this client session.
- **Ndb_api_pruned_scan_count_replica**: Number of scans that have been pruned to one partition by this replica.
- **Ndb_api_pruned_scan_count_slave**: Number of scans that have been pruned to one partition by this replica.
- **Ndb_api_range_scan_count**: Number of range scans that have been started by this MySQL Server (SQL node).
- **Ndb_api_range_scan_count_session**: Number of range scans that have been started in this client session.
- **Ndb_api_range_scan_count_replica**: Number of range scans that have been started by this replica.
- **Ndb_api_range_scan_count_slave**: Number of range scans that have been started by this replica.
- **Ndb_api_read_row_count**: Total number of rows that have been read by this MySQL Server (SQL node).
- **Ndb_api_read_row_count_session**: Total number of rows that have been read in this client session.
- **Ndb_api_read_row_count_replica**: Total number of rows that have been read by this replica.
- **Ndb_api_read_row_count_slave**: Total number of rows that have been read by this replica.
- **Ndb_api_scan_batch_count**: Number of batches of rows received by this MySQL Server (SQL node).
- **Ndb_api_scan_batch_count_session**: Number of batches of rows received in this client session.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- `Ndb_api_scan_batch_count_replica`: Number of batches of rows received by this replica.
- `Ndb_api_scan_batch_count_slave`: Number of batches of rows received by this replica.
- `Ndb_api_table_scan_count`: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).
- `Ndb_api_table_scan_count_session`: Number of table scans that have been started, including scans of internal tables, in this client session.
- `Ndb_api_table_scan_count_replica`: Number of table scans that have been started, including scans of internal tables, by this replica.
- `Ndb_api_table_scan_count_slave`: Number of table scans that have been started, including scans of internal tables, by this replica.
- `Ndb_api_trans_abort_count`: Number of transactions aborted by this MySQL Server (SQL node).
- `Ndb_api_trans_abort_count_session`: Number of transactions aborted in this client session.
- `Ndb_api_trans_abort_count_replica`: Number of transactions aborted by this replica.
- `Ndb_api_trans_abort_count_slave`: Number of transactions aborted by this replica.
- `Ndb_api_trans_close_count`: Number of transactions closed by this MySQL Server (SQL node); may be greater than sum of TransCommitCount and TransAbortCount.
- `Ndb_api_trans_close_count_session`: Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) in this client session.
- `Ndb_api_trans_close_count_replica`: Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this replica.
- `Ndb_api_trans_close_count_slave`: Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this replica.
- `Ndb_api_trans_commit_count`: Number of transactions committed by this MySQL Server (SQL node).
- `Ndb_api_trans_commit_count_session`: Number of transactions committed in this client session.
- `Ndb_api_trans_commit_count_replica`: Number of transactions committed by this replica.
- `Ndb_api_trans_commit_count_slave`: Number of transactions committed by this replica.
- `Ndb_api_trans_local_read_row_count`: Total number of rows that have been read by this MySQL Server (SQL node).
- `Ndb_api_trans_local_read_row_count_session`: Total number of rows that have been read in this client session.
- `Ndb_api_trans_local_read_row_count_replica`: Total number of rows that have been read by this replica.
- `Ndb_api_trans_local_read_row_count_slave`: Total number of rows that have been read by this replica.
- `Ndb_api_trans_start_count`: Number of transactions started by this MySQL Server (SQL node).
- `Ndb_api_trans_start_count_session`: Number of transactions started in this client session.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_trans_start_count_replica**: Number of transactions started by this replica.
- **Ndb_api_trans_start_count_slave**: Number of transactions started by this replica.
- **Ndb_api_uk_op_count**: Number of operations based on or using unique keys by this MySQL Server (SQL node).
- **Ndb_api_uk_op_count_session**: Number of operations based on or using unique keys in this client session.
- **Ndb_api_uk_op_count_replica**: Number of operations based on or using unique keys by this replica.
- **Ndb_api_uk_op_count_slave**: Number of operations based on or using unique keys by this replica.
- **Ndb_api_wait_exec_complete_count**: Number of times thread has been blocked while waiting for operation execution to complete by this MySQL Server (SQL node).
- **Ndb_api_wait_exec_complete_count_session**: Number of times thread has been blocked while waiting for operation execution to complete in this client session.
- **Ndb_api_wait_exec_complete_count_replica**: Number of times thread has been blocked while waiting for operation execution to complete by this replica.
- **Ndb_api_wait_exec_complete_count_slave**: Number of times thread has been blocked while waiting for operation execution to complete by this replica.
- **Ndb_api_wait_meta_request_count**: Number of times thread has been blocked waiting for metadata-based signal by this MySQL Server (SQL node).
- **Ndb_api_wait_meta_request_count_session**: Number of times thread has been blocked waiting for metadata-based signal in this client session.
- **Ndb_api_wait_meta_request_count_replica**: Number of times thread has been blocked waiting for metadata-based signal by this replica.
- **Ndb_api_wait_meta_request_count_slave**: Number of times thread has been blocked waiting for metadata-based signal by this replica.
- **Ndb_api_wait_nanos_count**: Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this MySQL Server (SQL node).
- **Ndb_api_wait_nanos_count_session**: Total time (in nanoseconds) spent waiting for some type of signal from data nodes in this client session.
- **Ndb_api_wait_nanos_count_replica**: Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica.
- **Ndb_api_wait_nanos_count_slave**: Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica.
- **Ndb_api_wait_scan_result_count**: Number of times thread has been blocked while waiting for scan-based signal by this MySQL Server (SQL node).
- **Ndb_api_wait_scan_result_count_session**: Number of times thread has been blocked while waiting for scan-based signal in this client session.
- **Ndb_api_wait_scan_result_count_replica**: Number of times thread has been blocked while waiting for scan-based signal by this replica.
- **Ndb_api_wait_scan_result_count_slave**: Number of times thread has been blocked while waiting for scan-based signal by this replica.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb_autoincrement_prefetch_sz**: NDB auto-increment prefetch size.
- **ndb_clear_apply_status**: Causes RESET SLAVE/RESET REPLICA to clear all rows from ndb_apply_status table; ON by default.
- **Ndb_cluster_node_id**: Node ID of this server when acting as NDB Cluster SQL node.
- **Ndb_config_from_host**: NDB Cluster management server host name or IP address.
- **Ndb_config_from_port**: Port for connecting to NDB Cluster management server.
- **Ndb_config_generation**: Generation number of the current configuration of the cluster.
- **Ndb_conflict_fn_epoch**: Number of rows that have been found in conflict by NDB$EPOCH() NDB replication conflict detection function.
- **Ndb_conflict_fn_epoch2**: Number of rows that have been found in conflict by NDB replication NDB$EPOCH2() conflict detection function.
- **Ndb_conflict_fn_epoch2_trans**: Number of rows that have been found in conflict by NDB replication NDB$EPOCH2_TRANS() conflict detection function.
- **Ndb_conflict_fn_epoch_trans**: Number of rows that have been found in conflict by NDB $EPOCH_TRANS() conflict detection function.
- **Ndb_conflict_fn_max**: Number of times that NDB replication conflict resolution based on "greater timestamp wins" has been applied to update and delete operations.
- **Ndb_conflict_fn_max_del_win**: Number of times that NDB replication conflict resolution based on outcome of NDB$MAX_DELETE_WIN() has been applied to update and delete operations.
- **Ndb_conflict_fn_max_ins**: Number of times that NDB replication conflict resolution based on "greater timestamp wins" has been applied to insert operations.
- **Ndb_conflict_fn_max_del_win_ins**: Number of times that NDB replication conflict resolution based on outcome of NDB$MAX_DEL_WIN_INS() has been applied to insert operations.
- **Ndb_conflict_fn_old**: Number of times that NDB replication "same timestamp wins" conflict resolution has been applied.
- **Ndb_conflict_last_conflict_epoch**: Most recent NDB epoch on this replica in which some conflict was detected.
- **Ndb_conflict_last_stable_epoch**: Most recent epoch containing no conflicts.
- **Ndb_conflict_reflected_op_discard_count**: Number of reflected operations that were not applied due error during execution.
- **Ndb_conflict_reflected_op_prepare_count**: Number of reflected operations received that have been prepared for execution.
- **Ndb_conflict_refresh_op_count**: Number of refresh operations that have been prepared.
- **ndb_conflict_role**: Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.
- **Ndb_conflict_trans_conflict_commit_count**: Number of epoch transactions committed after requiring transactional conflict handling.
- **Ndb_conflict_trans_detect_iter_count**: Number of internal iterations required to commit epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_conflict_trans_reject_count**: Number of transactions rejected after being found in conflict by transactional conflict function.

- **Ndb_conflict_trans_row_conflict_count**: Number of rows found in conflict by transactional conflict function. Includes any rows included in or dependent on conflicting transactions.

- **Ndb_conflict_trans_row_reject_count**: Total number of rows realigned after being found in conflict by transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.

- **ndb_data_node_neighbour**: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables.

- **ndb_default_column_format**: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.

- **ndb_deferred_constraints**: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

- **ndb_dbg_check_shares**: Check for any lingering shares (debug builds only).

- **ndb-schema-dist-timeout**: How long to wait before detecting timeout during schema distribution.

- **ndb_distribution**: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).

- **Ndb_epoch_delete_delete_count**: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist).

- **ndb_eventbuffer_free_percent**: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc.

- **ndb_eventbuffer_max_alloc**: Maximum memory that can be allocated for buffering events by NDB API. Defaults to 0 (no limit).

- **Ndb_execute_count**: Number of round trips to NDB kernel made by operations.

- **ndb_extra_logging**: Controls logging of NDB Cluster schema, connection, and data distribution events in MySQL error log.

- **ndb_force_send**: Forces sending of buffers to NDB immediately, without waiting for other threads.

- **ndb_fully_replicated**: Whether new NDB tables are fully replicated.

- **ndb_index_stat_enable**: Use NDB index statistics in query optimization.

- **ndb_index_stat_option**: Comma-separated list of tunable options for NDB index statistics; list should contain no spaces.

- **ndb_join_pushdown**: Enables pushing down of joins to data nodes.

- **Ndb_last_commit_epoch_server**: Epoch most recently committed by NDB.

- **Ndb_last_commit_epoch_session**: Epoch most recently committed by this NDB client.

- **ndb_log_apply_status**: Whether or not MySQL server acting as replica logs mysql.ndb_apply_status updates received from its immediate source in its own binary log, using its own server ID.

- **ndb_log_bin**: Write updates to NDB tables in binary log. Effective only if binary logging is enabled with --log-bin.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb_log_binlog_index**: Insert mapping between epochs and binary log positions into ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled.

- **ndb_log_empty_epochs**: When enabled, epochs in which there were no changes are written to ndb_apply_status and ndb_binlog_index tables, even when log_replica_updates or log_slave_updates is enabled.

- **ndb_log_empty_update**: When enabled, updates which produce no changes are written to ndb_apply_status and ndb_binlog_index tables, even when log_replica_updates or log_slave_updates is enabled.

- **ndb_log_exclusive_reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.

- **ndb_log_orig**: Whether id and epoch of originating server are recorded in mysql.ndb_binlog_index table. Set using --ndb-log-orig option when starting mysqld.

- **ndb_log_transaction_id**: Whether NDB transaction IDs are written into binary log (Read-only).

- **ndb_log_transaction_compression**: Whether to compress NDB binary log; can also be enabled on startup by enabling --binlog-transaction-compression option.

- **ndb_log_transaction_compression_level_zstd**: The ZSTD compression level to use when writing compressed transactions to the NDB binary log.

- **ndb_metadata_check**: Enable auto-detection of NDB metadata changes with respect to MySQL data dictionary; enabled by default.

- **ndb_metadata_check_interval**: Interval in seconds to perform check for NDB metadata changes with respect to MySQL data dictionary.

- **Ndb_metadata_detected_count**: Number of times NDB metadata change monitor thread has detected changes.

- **Ndb_metadata_excluded_count**: Number of NDB metadata objects that NDB binlog thread has failed to synchronize.

- **ndb_metadata_sync**: Triggers immediate synchronization of all changes between NDB dictionary and MySQL data dictionary; causes ndb_metadata_check and ndb_metadata_check_interval values to be ignored. Resets to false when synchronization is complete.

- **Ndb_metadata_synced_count**: Number of NDB metadata objects which have been synchronized.

- **Ndb_number_of_data_nodes**: Number of data nodes in this NDB cluster; set only if server participates in cluster.

- **ndb-optimization-delay**: Number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.

- **ndb_optimized_node_selection**: Determines how SQL node chooses cluster data node to use as transaction coordinator.

- **Ndb_pruned_scan_count**: Number of scans executed by NDB since cluster was last started where partition pruning could be used.

- **Ndb_pushed_queries_defined**: Number of joins that API nodes have attempted to push down to data nodes.

- **Ndb_pushed_queries_dropped**: Number of joins that API nodes have tried to push down, but failed.

- **Ndb_pushed_queries_executed**: Number of joins successfully pushed down and executed on data nodes.
• **Ndb_pushed_reads**: Number of reads executed on data nodes by pushed-down joins.

• **ndb_read_backup**: Enable read from any replica for all NDB tables; use `NDB_TABLE=READ_BACKUP={0|1}` with CREATE TABLE or ALTER TABLE to enable or disable for individual NDB tables.

• **ndb_recv_thread_activation_threshold**: Activation threshold when receive thread takes over polling of cluster connection (measured in concurrently active threads).

• **ndb_recv_thread_cpu_mask**: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

• **Ndb_replica_max_replicated_epoch**: Most recently committed NDB epoch on this replica. When this value is greater than or equal to `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

• **ndb_replica_batch_size**: Batch size in bytes for replica applier.

• **ndb_report_thresh_binlog_epoch_slip**: NDB 7.5 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates `BUFFERED_EPOCHS_OVER_THRESHOLD` event buffer status message; prior to NDB 7.5: Threshold for number of epochs to lag behind before reporting binary log status.

• **ndb_report_thresh_binlog_mem_usage**: Threshold for percentage of free memory remaining before reporting binary log status.

• **ndb_row_checksum**: When enabled, set row checksums; enabled by default.

• **Ndb_scan_count**: Total number of scans executed by NDB since cluster was last started.

• **ndb_schema_dist_lock_wait_timeout**: Time during schema distribution to wait for lock before returning error.

• **ndb_schema_dist_timeout**: Time to wait before detecting timeout during schema distribution.

• **ndb_schema_dist_upgrade_allowed**: Allow schema distribution table upgrade when connecting to NDB.

• **ndb_show_foreign_key_mock_tables**: Show mock tables used to support foreign_key_checks=0.

• **ndb_slave_conflict_role**: Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.

• **Ndb_slave_max_replicated_epoch**: Most recently committed NDB epoch on this replica. When this value is greater than or equal to `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

• **Ndb_system_name**: Configured cluster system name; empty if server not connected to NDB.

• **ndb_table_no_logging**: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). Setting in effect when table is created with or altered to use NDBCLUSTER persists for table's lifetime.

• **ndb_table_temporary**: NDB tables are not persistent on disk: no schema files are created and tables are not logged.

• **Ndb_trans_hint_count_session**: Number of transactions using hints that have been started in this session.

• **ndb_use_copying_alter_table**: Use copying ALTER TABLE operations in NDB Cluster.
• **ndb_use_exact_count**: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query.

• **ndb_use_transactions**: Set to OFF, to disable transaction support by NDB. Not recommended except in certain special cases; see documentation for details.

• **ndb_version**: Shows build and NDB engine version as an integer.

• **ndb_version_string**: Shows build information including NDB engine version in ndb-x.y.z format.

• **ndbcluster**: Enable NDB Cluster (if this version of MySQL supports it). Disabled by `--skip-ndbcluster`.

• **ndbinfo**: Enable ndbinfo plugin, if supported.

• **ndbinfo_database**: Name used for NDB information database; read only.

• **ndbinfo_max_bytes**: Used for debugging only.

• **ndbinfo_max_rows**: Used for debugging only.

• **ndbinfo_offline**: Put ndbinfo database into offline mode, in which no rows are returned from tables or views.

• **ndbinfo_show_hidden**: Whether to show ndbinfo internal base tables in mysql client; default is OFF.

• **ndbinfo_table_prefix**: Prefix to use for naming ndbinfo internal base tables; read only.

• **ndbinfo_version**: ndbinfo engine version; read only.

• **replica_allow_batching**: Turns update batching on and off for replica.

• **server_id_bits**: Number of least significant bits in server_id actually used for identifying server, permitting NDB API applications to store application data in most significant bits. server_id must be less than 2 to power of this value.

• **skip-ndbcluster**: Disable NDB Cluster storage engine.

• **slave_allow_batching**: Turns update batching on and off for replica.

• **transaction_allow_batching**: Allows batching of statements within one transaction. Disable AUTOCOMMIT to use.

### 25.4.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- **my.cnf**: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.

- **config.ini**: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. *config.ini* contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the config.ini File.

**Caching of configuration data.** NDB uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the
configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the --initial option.** When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the --reload option.** The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server’s cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.

- **The management server is started using --config-cache=FALSE.** This disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.

- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server’s node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

**Note**

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see Section 25.5.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”.

We are continuously making improvements in NDB Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we try to let NDB Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”.

### 25.4.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you should update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

**Note**

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```sql
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 8.4)
```
NDB Cluster Configuration Files

# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
# IMPORTANT: When starting the management server with this option in the
# configuration file, the use of --initial or --reload on the command line when
# invoking ndb_mgmd is also required.
[ndb_mgmd]
config-file=/etc/config.ini

(For more information on connection strings, see Section 25.4.3.3, “NDB Cluster Connection Strings”.)

# my.cnf
# example additions to my.cnf for NDB Cluster
# (works on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186

---

Important

Once you have started a mysqld process with the NDBCLUSTER and ndb-connectstring parameters in the [mysqld] in the my.cnf file as shown previously, you cannot execute any CREATE TABLE or ALTER TABLE statements without having actually started the cluster. Otherwise, these statements fail with an error. This is by design.

You may also use a separate [mysql_cluster] section in the cluster my.cnf file for settings to be read and used by all executables:

# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186

For additional NDB variables that can be set in the my.cnf file, see NDB Cluster System Variables.

The NDB Cluster global configuration file is by convention named config.ini (but this is not required). If needed, it is read by ndb_mgmd at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using --config-file=path_name with ndb_mgmd on the command line. This option has no default value, and is ignored if ndb_mgmd uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (:) as well as the equal sign (=); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in config.ini. To create a default value section, simply add the word default to the section name. For example, an [ndbd]
section contains parameters that apply to a particular data node, whereas an [ndbd default] section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an [ndbd default] section that contains a DataMemory line to specify the data memory size.

If used, the [ndbd default] section must precede any [ndbd] sections in the configuration file. This is also true for default sections of any other type.

**Note**

In some older releases of NDB Cluster, there was no default value for NoOfReplicas, which always had to be specified explicitly in the [ndbd default] section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the management server)
# The first MySQL Server can be started from any host. The second can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

**Note**

The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for production settings. See Section 25.4.3.2, “Recommended Starting Configuration for NDB Cluster”, which provides a more complete example starting configuration.

Each node has its own section in the config.ini file. For example, this cluster has two data nodes, so the preceding configuration file contains two [ndbd] sections defining these nodes.

**Note**

Do not place comments on the same line as a section heading in the config.ini file; this causes the management server not to start because it cannot parse the configuration file in such cases.

**Sections of the config.ini File**

There are six different sections that you can use in the config.ini configuration file, as described in the following list:
• **[computer]**: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but may be used as a convenience when setting up a large cluster. See Section 25.4.3.4, “Defining Computers in an NDB Cluster”, for more information.

• **[ndbd]**: Defines a cluster data node (ndbd process). See Section 25.4.3.6, “Defining NDB Cluster Data Nodes”, for details.

• **[mysqld]**: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

• **[mgm]** or **[ndb_mgmd]**: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 25.4.3.5, “Defining an NDB Cluster Management Server”.

• **[tcp]**: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default transport protocol. Normally, **[tcp]** or **[tcp default]** sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 25.4.3.10, “NDB Cluster TCP/IP Connections”, for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 25.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections” to be of interest in some cases.)

• **[shm]**: Defines shared-memory connections between nodes. In MySQL 8.4, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 25.4.3.12, “NDB Cluster Shared-Memory Connections”.

• **[sci]**: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 8.4.

You can define default values for each section. If used, a default section should come before any other sections of that type. For example, an **[ndbd default]** section should appear in the configuration file before any **[ndbd]** sections.

NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server my.cnf or my.ini files.

### 25.4.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster’s data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.
Starting config.ini file. The following *config.ini* file is a recommended starting point for configuring a cluster running NDB Cluster 8.4:

```ini
# TCP PARAMETERS
[tcp default]
SendBufferMemory = 2M
ReceiveBufferMemory = 2M

# Increasing the sizes of these 2 buffers beyond the default values helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS
[ndb_mgmd default]
DataDir = /path/to/management/server/data/directory

# It is possible to use a different data directory for each management server, but for ease of administration it is preferable to be consistent.

[ndb_mgmd]
HostName = management-server-A-hostname
NodeId = management-server-A-nodeid

[ndb_mgmd]
HostName = management-server-B-hostname
NodeId = management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an arbitrator in the event of network partitioning, and so is recommended for high availability. Each management server must be identified by a HostName. You may for the sake of convenience specify a NodeId for any management server, although one is allocated for it automatically; if you do so, it must be in the range 1-255 inclusive and must be unique among all IDs specified for cluster nodes.

# DATA NODE PARAMETERS
[ndbd default]
NoOfReplicas = 2

# Using two fragment replicas is recommended to guarantee availability of data; using only one fragment replica does not provide any redundancy, which means that the failure of a single data node causes the entire cluster to shut down. It is also possible (but not required) to use more than two fragment replicas, although two fragment replicas are sufficient to provide high availability.

LockPagesInMainMemory = 1

# On Linux and Solaris systems, setting this parameter locks data node processes into memory. Doing so prevents them from swapping to disk, which can severely degrade cluster performance.

DataMemory = 3456M

# The value provided for DataMemory assumes 4 GB RAM per data node. However, for best results, you should first calculate the memory that would be used based on the data you actually plan to store (you may find the `ndb_size.pl` utility helpful in estimating this), then allow an extra 20% over the calculated values. Naturally, you should ensure that each data node host has at least as much physical memory as the sum of these two values.

# ODirect = 1

# Enabling this parameter causes NDDBCLUSTER to try using O_DIRECT writes for local checkpoints and redo logs; this can reduce load on CPUs. We recommend doing so when using NDB Cluster on systems running Linux kernel 2.6 or later.
```

---

3866
NoOfFragmentLogFiles = 300
DataDir = path/to/data/node/data/directory
MaxNoOfConcurrentOperations = 100000
SchedulerSpinTimer = 400
SchedulerExecutionTimer = 100
RealTimeScheduler = 1
# Setting these parameters allows you to take advantage of real-time scheduling of NDB threads to achieve increased throughput when using ndbd. They are not needed when using ndbmtd; in particular, you should not set RealTimeScheduler for ndbmtd data nodes.
TimeBetweenGlobalCheckpoints = 1000
TimeBetweenEpochs = 200
RedoBuffer = 32M
# CompressedLCP = 1
# CompressedBackup = 1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local checkpoint files and backup files to be compressed, which can result in a space savings of up to 50% over noncompressed LCPs and backups.
# MaxNoOfLocalScans = 64
MaxNoOfTables = 1024
MaxNoOfOrderedIndexes = 256
[ndbd]
HostName = data-node-A-hostname
# NodeId = data-node-A-nodeid
LockExecuteThreadToCPU = 1
LockMaintThreadsToCPU = 0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER threads to specific CPUs
[ndbd]
HostName = data-node-B-hostname
# NodeId = data-node-B-nodeid
LockExecuteThreadToCPU = 1
LockMaintThreadsToCPU = 0
# You must have an [ndbd] section for every data node in the cluster; each of these sections must include a HostName. Each section may optionally include a NodeId for convenience, but in most cases, it is sufficient to allow the cluster to allocate node IDs dynamically. If you do specify the node ID for a data node, it must be in the range 1 to 144 inclusive and must be unique among all IDs specified for cluster nodes.
# SQL NODE / API NODE PARAMETERS
[mysqld]
# HostName = sql-node-A-hostname
# NodeId = sql-node-A-nodeid
[mysqld]
# Each API or SQL node that connects to the cluster requires a [mysqld] or [api] section of its own. Each such section defines a connection "slot"; you should have at least as many of these sections in the config.ini file as the total number of API nodes and SQL nodes that you wish to have connected to the cluster at any given time. There is no performance or other penalty for having extra slots available in case you find later that you want or need more API or SQL nodes to connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section, then any API or SQL node may use that slot to connect to the cluster. You may wish to use an explicit HostName for one connection slot to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.

Required my.cnf options for SQL nodes. MySQL servers acting as NDB Cluster SQL nodes
must always be started with the --ndbcluster and --ndb-connectstring options, either on the
command line or in my.cnf.

25.4.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (ndb_mgmd), each node that is part
of an NDB Cluster requires a connection string that points to the management server's location.
This connection string is used in establishing a connection to the management server as well as in
performing other tasks depending on the node's role in the cluster. The syntax for a connection string is
as follows:

[nodeid=node_id,] host-definition[, host-definition[, ...]]

host-definition:
  host_name[:port_number]

node_id is an integer greater than or equal to 1 which identifies a node in config.ini. host_name
is a string representing a valid Internet host name or IP address. port_number is an integer referring
to a TCP/IP port number.

element 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200"
element 2 (short):   "myhost1"

localhost:1186 is used as the default connection string value if none is provided. If port_num is
omitted from the connection string, the default port is 1186. This port should always be available on the
network because it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/
port-numbers for details).

By listing multiple host definitions, it is possible to designate several redundant management servers.
An NDB Cluster data or API node attempts to contact successive management servers on each host in
the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes
having multiple network interfaces for connecting to management servers. A bind address consists of
a hostname or network address and an optional port number. This enhanced syntax for connection
strings is shown here:

[nodeid=node_id, [bind-address=host-definition,]
  host-definition[, bind-address=host-definition]
  host-definition[, bind-address=host-definition]
[, ...]]

host-definition:
  host_name[:port_number]

If a single bind address is used in the connection string prior to specifying any management hosts,
then this address is used as the default for connecting to any of them (unless overridden for a given
management server; see later in this section for an example). For example, the following connection
string causes the node to use 198.51.100.242 regardless of the management server to which it
connects:

bind-address=198.51.100.242, poseidon:1186, perch:1186

If a bind address is specified following a management host definition, then it is used only for connecting
to that management node. Consider the following connection string:
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242

In this case, the node uses localhost to connect to the management server running on the host named poseidon and 198.51.100.242 to connect to the management server running on the host named perch.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, localhost is used for connecting to the management server running on host poseidon; since 198.51.100.242 is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts perch and orca:

bind-address=198.51.100.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200

There are a number of different ways to specify the connection string:

• Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

• It is also possible to set the connection string for all nodes in the cluster at once by placing it in a [mysql_cluster] section in the management server's my.cnf file.

• For backward compatibility, two other options are available, using the same syntax:
  1. Set the NDB_CONNECTSTRING environment variable to contain the connection string.
  2. Write the connection string for each executable into a text file named Ndb.cfg and place this file in the executable’s startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the my.cnf file for each executable.

### 25.4.3.4 Defining Computers in an NDB Cluster

The [computer] section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

• **Id**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial System Restart:&lt;br&gt;Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>
This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

**Important**

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- **HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This is the computer's hostname or IP address.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.7 NDB Cluster restart types**

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

### 25.4.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

**Note**

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` is assumed for both.

- **Id**
Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- `NodeId`
Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

**Note**

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144.

**NodeId** is the preferred parameter name to use when identifying management nodes. Although the older **Id** continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

<table>
<thead>
<tr>
<th>ExecuteOnComputer</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
</tr>
<tr>
<td><strong>Default</strong></td>
</tr>
<tr>
<td><strong>Range</strong></td>
</tr>
<tr>
<td><strong>Deprecated</strong></td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
</tr>
</tbody>
</table>

This refers to the **Id** set for one of the computers defined in a [computer] section of the config.ini file.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the **HostName** parameter instead.

<table>
<thead>
<tr>
<th>PortNumber</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
</tr>
<tr>
<td><strong>Default</strong></td>
</tr>
<tr>
<td><strong>Range</strong></td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
</tr>
</tbody>
</table>
This is the port number on which the management server listens for configuration requests and management commands.

- **HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the management node is to reside. Use `HostName` to specify a host name other than `localhost`.

- **LocationDomainId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Assigns a management node to a specific **availability domain** (also known as an availability zone) within a cloud. By informing `NDB` which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use `NDB` transporters' WAN support without any further manual intervention.
• The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

• The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

LocationDomainId takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

• LogDestination

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>{CONSOLE, SYSLOG, FILE}</td>
</tr>
<tr>
<td>Default</td>
<td>FILE: filename=ndb_nodeid_cluster.log, maxsize=1000000, maxfiles=6</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies where to send cluster logging information. There are three options in this regard—CONSOLE, SYSLOG, and FILE—with FILE being the default:

• CONSOLE outputs the log to stdout:

  CONSOLE

• SYSLOG sends the log to a syslog facility, possible values being one of auth, authpriv, cron, daemon, ftp, kern, lpr, mail, news, syslog, user, uucp, local0, local1, local2, local3, local4, local5, local6, or local7.

  SYSLOG:facility=syslog

Note

Not every facility is necessarily supported by every operating system.
• **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- **filename**: The name of the log file.

  The default log file name used in such cases is `ndb_nodeid_cluster.log`.

- **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.

- **maxfiles**: The maximum number of log files.

```plaintext
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the **FILE** parameter is `FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```plaintext
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

• **ArbitrationRank**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart</strong>: Requires a <strong>rolling restart</strong> of the cluster. <em>(NDB 8.4.0)</em></td>
</tr>
</tbody>
</table>

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. **ArbitrationRank** can take one of the following values:

- **0**: The node is never used as an arbitrator.
- **1**: The node has high priority; that is, it is preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which is used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its **ArbitrationRank** to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting **ArbitrationRank** to 0 on all management and SQL nodes, or by setting the **Arbitration** parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting **Arbitration** causes any settings for **ArbitrationRank** to be disregarded.
• **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

• **DataDir**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This specifies the directory where output files from the management server are placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination`, as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

• **PortNumberStats**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.
NDB Cluster Configuration Files

- **Wan**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

  Use WAN TCP setting as default.

- **HeartbeatThreadPriority**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

  Set the scheduling policy and priority of heartbeat threads for management and API nodes.

  The syntax for setting this parameter is shown here:

  ```
  HeartbeatThreadPriority = policy[, priority]
  
  policy:
  (FIFO | RR)
  ```

  When setting this parameter, you must specify a policy. This is one of FIFO (first in, first out) or RR (round robin). The policy value is followed optionally by the priority (an integer).

- **ExtraSendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32G</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.
NDB Cluster Configuration Files

- **RequireTls**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type**: Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)

If this parameter is set to `true`, a client, once connected to this management node, must be authenticated using TLS before the connection can be used for anything else.

- **TotalSendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type**: Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- **HeartbeatIntervalMgmdMgmd**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type**: Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)
Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing config.ini files. For more information about issues arising when using multiple management nodes, see Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>

<td>Initial</td>
<td>Data nodes must be restarted using the --initial option</td>
</tr>
</tbody>
</table>

### 25.4.3.6 Defining NDB Cluster Data Nodes

The [ndbd] and [ndbd default] sections are used to configure the behavior of the cluster's data nodes.

[ndbd] and [ndbd default] are always used as the section names whether you are using ndbd or ndbmtd binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is ExecuteOnComputer; this must be defined in the local [ndbd] section.

The parameter NoOfReplicas should be defined in the [ndbd default] section, as it is common to all Cluster data nodes. It is not strictly necessary to set NoOfReplicas, but it is good practice to set it explicitly.

Most data node parameters are set in the [ndbd default] section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the [ndbd] section. Where present, HostName and NodeId must be defined in the local [ndbd] section, and not in any other section of config.ini. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use K, M, or G as a suffix to indicate units of 1024, 1024x1024, or 1024x1024x1024. (For example, 100K means 100 x 1024 = 102400.)
Parameter names and values are case-insensitive, unless used in a MySQL Server `my.cnf` or `my.ini` file, in which case they are case-sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

All of these parameters also apply to `ndbmtd` (the multithreaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmtd` only; these have no effect when used with `ndbd`. For more information, see Multi-Threading Configuration Parameters (ndbmtd). See also Section 25.5.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

**Identifying data nodes.** The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- **NodeId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>

</tr>
</tbody>
</table>

A unique node ID is used as the node’s address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 144 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the only supported parameter name to use when identifying data nodes.
restart of the cluster. (NDB 8.4.0)

This refers to the Id set for one of the computers defined in a [computer] section.

Important
This parameter is deprecated, and is subject to removal in a future release. Use the HostName parameter instead.

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and HostName is not sufficient for distinguishing among processes. Intended for use in testing.

- HostName

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>

<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the</td>
</tr>
</tbody>
</table>
Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an [ndbd] section or (if you need to do this for multiple data nodes) the [ndbd default] section of the config.ini file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

Note
Connections from data nodes to management nodes is done using the ndb_mgmd management port (the management server’s PortNumber) so outgoing connections to that port from any data nodes should always be permitted.

• TcpBind_INADDR_ANY
Setting this parameter to TRUE or 1 binds IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections). The default is FALSE (0).

• NodeGroup

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65536</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial System Restart: Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the [ndbd default] section of the config.ini file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The NodeGroup parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a NodeGroup value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 25.6.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

3882
**LocationDomainId**

Assigns a data node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

**LocationDomainId** takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

**NoOfReplicas**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial System Restart:</strong> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>
This global parameter can be set only in the `[ndbd default]` section, and defines the number of fragment replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes is the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2. This is the recommended value for most production environments. Setting this parameter's value to 3 or 4 is also supported.

**Warning**

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The number of data nodes in the cluster must be evenly divisible by the value of this parameter. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

• **DataDir**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>.</td>
</tr>
<tr>

<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with <code>--initial</code>. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

• **FileSystemPath**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

**Default**

<table>
<thead>
<tr>
<th>DataDir</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type**

| Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with --initial. (NDB 8.4.0) |

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

**Note**

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- **BackupDataDir**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPath</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type**

| Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with --initial. (NDB 8.4.0) |

This parameter specifies the directory in which backups are placed.

**Important**

The string 'BACKUP' is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the effective default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

### Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to
understand how `DataMemory` is used, as it usually needs to be updated to reflect actual usage by the cluster.

**Note**

`IndexMemory` is deprecated, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.

- **DataMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>98M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 16T</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 30000 bytes.

Resources assigned to `DataMemory` are used for storing all data and indexes. (Any memory configured as `IndexMemory` is automatically added to that used by `DataMemory` to form a common resource pool.)

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:
NDB Cluster Configuration Files

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for DataMemory is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

</tbody>
</table>

The IndexMemory parameter is deprecated (and subject to future removal); any memory assigned to IndexMemory is allocated instead to the same pool as DataMemory, which is solely responsible for all resources needed for storing data and indexes in memory. In NDB 8.4, the use of IndexMemory in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

\[
\text{size} = ( (\text{fragments} * 32\text{K}) + (\text{rows} * 18) ) * \text{fragment_replicas}
\]

\(\text{fragments}\) is the number of fragments, \(\text{fragment_replicas}\) is the number of fragment replicas (normally 2), and \(\text{rows}\) is the number of rows. If a table has one million rows, eight fragments, and two fragment replicas, the expected index memory usage is calculated as shown here:

\[
(8 * 32\text{K}) + (1000000 * 18) = 262144 + 18000000 * 2 = 18262144 * 2 = 36524288 \text{ bytes} = \sim 35\text{MB}
\]

Index statistics for ordered indexes (when these are enabled) are stored in the mysql.ndb_index_stat_sample table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

\[
\text{sample_size} = \text{key_size} + ((\text{key_attributes} + 1) * 4)
\]

\[
\text{sample_rows} = \text{IndexStatSaveSize} * ((0.01 * \text{IndexStatSaveScale} * \log_2(\text{rows} * \text{sample_size})) + 1)
\]
In the preceding formula, \textit{key\_size} is the size of the ordered index key in bytes, \textit{key\_attributes} is the number of attributes in the ordered index key, and \textit{rows} is the number of rows in the base table.

Assume that table \texttt{t1} has 1 million rows and an ordered index named \texttt{ix1} on two four-byte integers. Assume in addition that \texttt{IndexStatSaveSize} and \texttt{IndexStatSaveScale} are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

\[
\text{sample\_size} = 8 + ((1 + 2) * 4) = 20 \text{ bytes}
\]

\[
\text{sample\_rows} = 32\text{K} * ((0.01 * 100 * \log_2(1000000*20)) + 1) / 20
\]
\[
= 32768 * (1 * -16.811 +1) / 20
\]
\[
= 32768 * -17.811 / 20
\]
\[
= -29182 \text{ rows}
\]

The expected index memory usage is thus \(2 * 18 * 29182 = \sim 1050550 \text{ bytes} \).

The minimum and default value for this parameter is 0 (zero).

**StringMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>% or bytes</td>
</tr>
<tr>
<td>Default</td>
<td>25</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter determines how much memory is allocated for strings such as table names, and is specified in an \texttt{[ndbd]} or \texttt{[ndbd default]} section of the \texttt{config.ini} file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of .FRM files, \texttt{MaxNoOfTriggers}, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many NDB tables (1000 or more), it is possible to get Error 773 \texttt{Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error}, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```sql
CREATE TABLE example {
    a INT NOT NULL,
}
b INT NOT NULL,
c INT NOT NULL,
PRIMARY KEY(a),
UNIQUE(b)
) ENGINE=NDDBCLUSTER;

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns a and b consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with b as primary key and a as a column. This other table consumes an additional 29 bytes of index memory per record in the example table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both IndexMemory and DataMemory is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two fragment replicas, there are two node groups. Thus, the total data memory available is 2 × DataMemory for each data node.

It is highly recommended that DataMemory and IndexMemory be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

DataMemory can be changed, but decreasing it can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

MinFreePct. A proportion (5% by default) of data node resources including DataMemory is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the MinFreePct data node configuration parameter (default 5).

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction parameters. The next few [ndbd] parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the
system. **MaxNoOfConcurrentTransactions** sets the number of parallel transactions possible in a node. **MaxNoOfConcurrentOperations** sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially **MaxNoOfConcurrentOperations**) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

**MaxDMLOperationsPerTransaction** sets the maximum number of DML operations that can be performed in a given transaction.

- **MaxNoOfConcurrentTransactions**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4096</td>
</tr>
<tr>
<td>Range</td>

<tr>
<td>Deprecated</td>
<td>Yes (in NDB 8.0)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

\[
\text{TotalNoOfConcurrentTransactions} = (\text{maximum number of tables accessed in any single transaction} + 1) * \text{number of SQL nodes}
\]

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then \(10 * 11 = 110\) transaction records are required for this transaction, per MySQL server, or \(110 * 10 = 1100\) transaction records total. Each data node can be expected to handle TotalNoOfConcurrentTransactions / number of data nodes. For an NDB Cluster having 4 data nodes, this would mean setting MaxNoOfConcurrentTransactions on each data node to 1100 / 4 = 275. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's MaxNoOfConcurrentTransactions is sufficient to cover a number of transactions equal to TotalNoOfConcurrentTransactions / number of node groups. If this cluster has a single node group, then MaxNoOfConcurrentTransactions should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for MaxNoOfConcurrentTransactions should always be no more than the value of MaxNoOfConcurrentOperations.
This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- **MaxNoOfConcurrentOperations**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>32K</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to total number of concurrent operations / number of node groups. (In the case where there
is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` is always used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- **MaxNoOfLocalOperations**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>UNDEFINED</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 8.0)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

By default, this parameter is calculated as `1.1 × MaxNoOfConcurrentOperations`. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

This parameter is deprecated and subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the `TransactionMemory` parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.
NDB Cluster Configuration Files

- **MaxDMLOperationsPerTransaction**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>operations (DML)</td>
</tr>
<tr>
<td>Default</td>
<td>4294967295</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967295</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations.

The value of this parameter cannot exceed that set for MaxNoOfConcurrentOperations.

**Transaction temporary storage.** The next set of [ndbd](https://example.com) parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- **MaxNoOfConcurrentIndexOperations**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>8K</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 8.0)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter MaxNoOfConcurrentOperations.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.
This parameter is deprecated and subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the `TransactionMemory` parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

### MaxNoOfFiredTriggers

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 8.0)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

This parameter is deprecated and subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the `TransactionMemory` parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

### TransactionBufferMemory

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for
these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000 × 128 bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains 4000 × 16 = 62.5KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Transaction resource allocation parameters.** The parameters in the following list are used to allocate transaction resources in the transaction coordinator (DBTC). Leaving any one of these set to the default (0) dedicates transaction memory for 25% of estimated total data node usage for the corresponding resource. The actual maximum possible values for these parameters are typically limited by the amount of memory available to the data node; setting them has no impact on the total amount of memory allocated to the data node. In addition, you should keep in mind that they control numbers of reserved internal records for the data node independent of any settings for `MaxDMLOperationsPerTransaction`, `MaxNoOfConcurrentIndexOperations`, `MaxNoOfConcurrentOperations`, `MaxNoOfConcurrentScans`, `MaxNoOfConcurrentTransactions`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalScans`, or `TransactionBufferMemory` (see Transaction parameters and Transaction temporary storage).

Number of simultaneous fragment scans having dedicated resources on one data node.

- **ReservedTransactionBufferMemory**

### Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.

- **TransactionMemory**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0</td>
<td>0 - 16384G</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Important</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A number of configuration parameters are incompatible with <strong>TransactionMemory</strong>; it is not possible to set any of these parameters concurrently with <strong>TransactionMemory</strong>, and if you attempt to do so, the management server is unable to start (see Parameters incompatible with <strong>TransactionMemory</strong>).</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This parameter determines the memory (in bytes) allocated for transactions on each data node. Setting of transaction memory is handled as follows:

- If **TransactionMemory** is set, this value is used for determining transaction memory.
• Otherwise, transaction memory is calculated as it was previous to NDB 8.0.

**Parameters incompatible with TransactionMemory.** The following parameters cannot be used concurrently with TransactionMemory and are therefore deprecated:

- MaxNoOfConcurrentIndexOperations
- MaxNoOfFiredTriggers
- MaxNoOfLocalOperations
- MaxNoOfLocalScans

Explicitly setting any of the parameters just listed when TransactionMemory has also been set in the cluster configuration file (config.ini) keeps the management node from starting.

For more information regarding resource allocation in NDB Cluster data nodes, see Section 25.4.3.13, “Data Node Memory Management”.

**Scans and buffering.** There are additional [ndbd] parameters in the Dblqh module (in ndb/src/kernel/blocks/Dblqh/Dblqh.hpp) that affect reads and updates. These include ZATTRINBUF_FILESIZE, set by default to 10000 × 128 bytes (1250KB) and ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- **BatchSizePerLocalScan**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>

<thead>
<tr>
<th>Restart Type</th>
<th>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</th>
</tr>
</thead>
</table>

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- **MaxFKBuildBatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>16 - 512</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Restart Type</th>
<th>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</th>
</tr>
</thead>
</table>

Maximum scan batch size used for building foreign keys. Increasing the value set for this parameter may speed up building of foreign key builds at the expense of greater impact to ongoing traffic.

- **MaxNoOfConcurrentScans**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>2 - 500</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Restart Type</th>
<th>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</th>
</tr>
</thead>
</table>

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain MaxNoOfConcurrentScans scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is
an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of \texttt{MaxNoOfConcurrentScans} is 256. The maximum value is 500.

- \textbf{MaxNoOfLocalScans}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4 \ast MaxNoOfConcurrentScans \ast \text{[# of data nodes]} + 2</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 8.0)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart}: Requires a \texttt{rolling restart} of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

\[ 4 \ast \text{MaxNoOfConcurrentScans} \ast \text{[# data nodes]} + 2 \]

This parameter is deprecated and subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the \texttt{TransactionMemory} parameter; if you try to set values for both parameters in the cluster configuration file (\texttt{config.ini}), the management server refuses to start.

- \textbf{MaxParallelCopyInstances}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart}: Requires a \texttt{rolling restart} of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, \texttt{MaxParallelCopyInstances} provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- \textbf{MaxParallelScansPerFragment}
It is possible to configure the maximum number of parallel scans (TUP scans and TUX scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

- **MaxReorgBuildBatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>16 - 512</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

  Maximum scan batch size used for reorganization of table partitions. Increasing the value set for this parameter may speed up reorganization at the expense of greater impact to ongoing traffic.

- **MaxUIBuildBatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>16 - 512</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

  Maximum scan batch size used for building unique keys. Increasing the value set for this parameter may speed up such builds at the expense of greater impact to ongoing traffic.

**Memory Allocation**

- **MaxAllocate**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type or units</th>
<th>unsigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1G</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 8.0)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter was used in older versions of NDB Cluster, but has no effect in NDB 8.4. It is deprecated and subject to removal in a future release.

**Multiple Transporters**

NDB allocates multiple transporters for communication between pairs of data nodes. The number of transporters so allocated can be influenced by setting an appropriate value for the `NodeGroupTransporters` parameter introduced in that release.

**NodeGroupTransporters**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter determines the number of transporters used between nodes in the same node group. The default value (0) means that the number of transporters used is the same as the number of LDMs in the node. This should be sufficient for most use cases; thus it should seldom be necessary to change this value from its default.

Setting `NodeGroupTransporters` to a number greater than the number of LDM threads or the number of TC threads, whichever is higher, causes NDB to use the maximum of these two numbers of threads. This means that a value greater than this is effectively ignored.

**Hash Map Size**

**DefaultHashMapSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>LDM threads</td>
</tr>
<tr>
<td>Default</td>
<td>240</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 3840</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>
The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with DefaultHashMapSize equal to 3840 is not currently supported.

Logging and checkpointing. The following [ndbd] parameters control log and checkpoint behavior.

- **FragmentLogFileSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 1G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with --initial. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for NoOfFragmentLogFiles.

- **InitialNoOfOpenFiles**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>files</td>
</tr>
<tr>
<td>Default</td>
<td>27</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- **InitFragmentLogFiles**
By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. `InitFragmentLogFiles` takes either of two values:

- **SPARSE**: Fragment log files are created sparsely. This is the default value.

- **FULL**: Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the redo log.

**EnablePartialLcp**

When `true`, enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If `EnablePartialLcp` is disabled (`false`), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for
NDB Cluster Configuration Files

For each LCP, the default value is enabled (true). The proportion of space used by partial LCPS can be modified by the setting for the `RecoveryWork` configuration parameter.

For more information about files and directories used for full and partial LCPs, see NDB Cluster Data Node File System Directory.

Setting this parameter to false also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

- `LcpScanProgressTimeout`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>second</td>
</tr>
<tr>
<td>Default</td>
<td>180</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type**

- **Node Restart:** Requires a rolling restart of the cluster.
  (NDB 8.4.0)

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

- `MaxNoOfOpenFiles`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type**

- **Node Restart:** Requires a rolling restart of the cluster.
  (NDB 8.4.0)

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- `MaxNoOfSavedMessages`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
</table>

3905
This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

• **MaxLCPStartDelay**

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set **MaxLCPStartDelay**, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the [ndbd default] section of the config.ini file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

• **NoOfFragmentLogFiles**
Requires a rolling restart of the cluster; each data node must be restarted with \texttt{--initial}.
(NDB 8.4.0)

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the \texttt{FragmentLogFileSize} parameter. In scenarios requiring a great many updates, the value for \texttt{NoOfFragmentLogFiles} may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (\textit{Out of log file space temporarily}). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

\begin{itemize}
\item \textbf{RecoveryWork}\end{itemize}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>25 - 100</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)}</td>
</tr>
</tbody>
</table>

Percentage of storage overhead for LCP files. This parameter has an effect only when \texttt{EnablePartialLcp} is true, that is, only when partial local checkpoints are enabled. A higher value means:

\begin{itemize}
\item Fewer records are written for each LCP, LCPs use more space
\end{itemize}
NDB Cluster Configuration Files

- More work is needed during restarts

A lower value for RecoveryWork means:

- More records are written during each LCP, but LCPs require less space on disk.
- Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting RecoveryWork to 60 means that the total size of an LCP is roughly $1 + 0.6 = 1.6$ times the size of the data to be checkpointed. This means that 60% more work is required during the restore phase of a restart compared to the work done during a restart that uses full checkpoints. (This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at $1 + (1 / \text{RecoveryWork})$ times the rate of data changes during checkpoints—thus, when RecoveryWork = 60, it is necessary to write at approximately $1 + (1 / 0.6) = 2.67$ times the change rate. In other words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting RecoveryWork = 40 means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.

The NDB source distribution includes a test program for simulating LCPs. lcp_simulator.cc can be found in storage/ndb/src/kernel/blocks/backup/. To compile and run it on Unix platforms, execute the commands shown here:

```bash
$> gcc lcp_simulator.cc
$> ./a.out
```

This program has no dependencies other than stdio.h, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of recovery_work, insert_work, and delete_work in the source and recompiling. For more information, see the source of the program.

- InsertRecoveryWork

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>40</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 70</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Restart Type</th>
<th>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</th>
</tr>
</thead>
</table>

Percentage of RecoveryWork used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when EnablePartialLcp is true, that is, only when partial local checkpoints are enabled.
### EnableRedoControl

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Enable adaptive checkpointing speed for controlling redo log usage.

When enabled (the default), `EnableRedoControl` allows the data nodes greater flexibility with regard to the rate at which they write LCPs to disk. More specifically, enabling this parameter means that higher write rates can be employed, so that LCPs can complete and redo logs be trimmed more quickly, thereby reducing recovery time and disk space requirements. This functionality allows data nodes to make better use of the higher rate of I/O and greater bandwidth available from modern solid-state storage devices and protocols, such as solid-state drives (SSDs) using Non-Volatile Memory Express (NVMe).

When **NDB** is deployed on systems whose I/O or bandwidth is constrained relative to those employing solid-state technology, such as those using conventional hard disks (HDDs), the `EnableRedoControl` mechanism can easily cause the I/O subsystem to become saturated, increasing wait times for data node input and output. In particular, this can cause issues with NDB Disk Data tables which have tablespaces or log file groups sharing a constrained I/O subsystem with data node LCP and redo log files; such problems potentially include node or cluster failure due to GCP stop errors. Set `EnableRedoControl` to **false** to disable it in such situations. Setting `EnablePartialLcp` to **false** also disables the adaptive calculation.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

**Note**

These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

### MaxNoOfAttributes

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>
This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like MaxNoOfAttributes, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfAttributes attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting MaxNoOfAttributes, it is important to prepare in advance for any ALTER TABLE statements that you might want to perform in the future. This is due to the fact, during the execution of ALTER TABLE on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (greatest_number_of_attributes) has 100 attributes, a good starting point for the value of MaxNoOfAttributes would be 6 * greatest_number_of_attributes = 600.

You should also estimate the average number of attributes per table and multiply this by MaxNoOfTables. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual ALTER TABLE after configuring the parameter. If this is not successful, increase MaxNoOfAttributes by another multiple of MaxNoOfTables and test it again.

• MaxNoOfTables

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>8 - 20320</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like MaxNoOfAttributes, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create
more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfTables tables.)

For each attribute that has a BLOB data type an extra table is used to store most of the BLOB data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. MaxNoOfOrderedIndexes sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart</td>
</tr>
</tbody>
</table>

The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).
For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the USING HASH option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note

The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

- **MaxNoOfTriggers**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an ordered index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- **MaxNoOfSubscriptions**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)
Each NDB table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for MaxNoOfSubscriptions is 0, which is treated as equal to MaxNoOfTables. Each subscription consumes 108 bytes.

- **MaxNoOfSubscribers**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter is of interest only when using NDB Cluster Replication. The default value is 0. It is treated as $2 \times \text{MaxNoOfTables} + 2 \times [\text{number of API nodes}]$. There is one subscription per NDB table for each of two MySQL servers (one acting as the replication source and the other as the replica). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-source replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of mysqld processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Clusters, with one mysqld attached to each cluster, and each of these mysqld processes acts as a source and as a replica, you should set \text{MaxNoOfSubscribers} equal to $3 \times \text{MaxNoOfTables}$.

For more information, see Section 25.7, “NDB Cluster Replication”.

- **MaxNoOfConcurrentSubOperations**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.
Boolean parameters. The behavior of data nodes is also affected by a set of [ndbd] parameters taking on boolean values. These parameters can each be specified as TRUE by setting them equal to 1 or Y, and as FALSE by setting them equal to 0 or N.

- **CompressedLCP**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 causes local checkpoint files to be compressed. The compression used is equivalent to gzip --fast, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the [ndbd default] section of the config.ini file).

**Important**

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

- **CrashOnCorruptedTuple**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When this parameter is enabled (the default), it forces a data node to shut down whenever it encounters a corrupted tuple.

- **Diskless**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>true</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial System Restart:</strong></td>
</tr>
</tbody>
</table>
Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.4.0)

It is possible to specify NDB Cluster tables as diskless, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run ndbd on a diskless computer.

Important
This feature causes the entire cluster to operate in diskless mode.

When this feature is enabled, NDB Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

Diskless is disabled by default.

- EncryptedFileSystem

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with --initial. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Encrypt LCP and tablespace files, including undo logs and redo logs. Disabled by default (0); set to 1 to enable.

Important
When file system encryption is enabled, you must supply a password to each data node when starting it, using one of the options --filesystem-password or --filesystem-password-from-stdin. Otherwise, the data node cannot start.

For more information, see Section 25.6.14, “File System Encryption for NDB Cluster”.

<td>0 - 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- **LockPagesInMainMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster’s real-time characteristics.

This parameter takes one of the integer values 0, 1, or 2, which act as shown in the following list:

- **0**: Disables locking. This is the default value.
- **1**: Performs the lock after allocating memory for the process.
- **2**: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (**LockPagesInMainMemory** uses the **mlockall** function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by **max locked memory**. For more information, see ulimit -l and http://linux.die.net/man/2/mlock).

**Note**

In older NDB Cluster releases, this parameter was a Boolean. 0 or **false** was the default setting, and disabled locking. 1 or **true** enabled locking of...
the process after its memory was allocated. NDB Cluster 8.4 treats `true` or `false` for the value of this parameter as an error.

**Important**

Beginning with glibc 2.10, glibc uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The glibc behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to glibc 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also [http://sourceware.org/bugzilla/show_bug.cgi?id=13137](http://sourceware.org/bugzilla/show_bug.cgi?id=13137) for more information concerning this issue.)

One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a jemalloc memory allocation library to take the place of that supplied with glibc.

- **ODirect**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Enabling this parameter causes NDB to attempt using O_DIRECT writes for LCP, backups, and redo logs, often lowering kswapd and CPU usage. When using NDB Cluster on Linux, enable ODirect if you are using a 2.6 or later kernel.

**ODirect** is disabled by default.

- **ODirectSyncFlag**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart</td>
</tr>
</tbody>
</table>

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to `fsync`. The setting for this parameter is ignored if at least one of the following conditions is true:

- **ODirect** is not enabled.
- **InitFragmentLogFiles** is set to **SPARSE**.

Disabled by default.

**RequireCertificate**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

If this parameter is set to **true**, the data node looks for a key and a valid and current certificate in the TLS search path, and cannot start if it does not find them.

**RequireTls**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

If this parameter is set to **true**, connections to this data node must be authenticated using TLS.

**RestartOnErrorInsert**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>error code</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart</strong>: Requires a rolling restart</td>
</tr>
</tbody>
</table>

(NDB 8.4.0)
NDB Cluster Configuration Files

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- **StopOnError**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and StopOnError is 0, the data node process is restarted.

Users of MySQL Cluster Manager should note that, when StopOnError equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See Starting and Stopping the Agent on Linux, for more information.

- **UseShm**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Enable a shared memory connection between this data node and the API node also running on this host. Set to 1 to enable.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of [ndbd] parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- **TimeBetweenWatchDogCheck**
To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- **TimeBetweenWatchDogCheckInitial**

This is similar to the TimeBetweenWatchDogCheck parameter, except that TimeBetweenWatchDogCheckInitial controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- **StartPartialTimeout**
Restart Type

Node Restart:
Requires a rolling restart of the cluster. (NDB 8.4.0)

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- **StartPartitionedTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEEFF)</td>
</tr>
</tbody>
</table>
| Restart Type       | Node Restart:
  Requires a rolling restart of the cluster. (NDB 8.4.0) |

If the cluster is ready to start after waiting for StartPartialTimeout milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If StartPartitionedTimeout is set to 0, the cluster waits indefinitely (2^{32}−1 ms, or approximately 49.71 days).

This parameter is overridden when performing an initial start or initial restart of the cluster.

- **StartFailureTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEEFF)</td>
</tr>
</tbody>
</table>
| Restart Type       | Node Restart:
  Requires a rolling restart of the cluster. (NDB 8.4.0) |

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a
data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- **StartNoNodeGroupTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>15000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When a data node is configured with Nodegroup = 65536, is regarded as not being assigned to any node group. When that is done, the cluster waits StartNoNodegroupTimeout milliseconds, then treats such nodes as though they had been added to the list passed to the --nowait-nodes option, and starts. The default value is 15000 (that is, the management server waits 15 seconds). Setting this parameter equal to 0 means that the cluster waits indefinitely.

**StartNoNodegroupTimeout** must be the same for all data nodes in the cluster; for this reason, you should always set it in the [ndbd default] section of the config.ini file, rather than for individual data nodes.

See Section 25.6.7, “Adding NDB Cluster Data Nodes Online”, for more information.

- **HeartbeatIntervalDbDb**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>5000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the
Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see `Network communication and latency`.

**HeartbeatOrder**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65535</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a
data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster.

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers host1 and host2, and that these data nodes make up 2 node groups, as shown in the following table:

Table 25.9 Four data nodes A, B, C, D running on two host computers host1, host2; each data node belongs to one of two node groups.

<table>
<thead>
<tr>
<th>Node Group</th>
<th>Nodes Running on host1</th>
<th>Nodes Running on host2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node Group 0:</td>
<td>Node A</td>
<td>Node B</td>
</tr>
<tr>
<td>Node Group 1:</td>
<td>Node C</td>
<td>Node D</td>
</tr>
</tbody>
</table>

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by NDB. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

Table 25.10 HeartbeatOrder values to force a heartbeat transition order of A->B->D->C->A.

<table>
<thead>
<tr>
<th>Node</th>
<th>HeartbeatOrder Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>10</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>30</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
</tr>
</tbody>
</table>

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
NDB Cluster Configuration Files

- 2 rolling restarts of the cluster in succession. All nodes must be restarted in the same order in both rolling restarts.

You can use DUMP 908 to observe the effect of this parameter in the data node logs.

- **ConnectCheckIntervalDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to HeartbeatIntervalDbDb milliseconds. Such a data node that further fails to respond within an interval of ConnectCheckIntervalDelay milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- **TimeBetweenLocalCheckpoints**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>number of 4-byte words, as base-2 logarithm</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 31</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-
byte words, so that the default value 20 means 4MB \(4 \times 2^{20}\) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting \texttt{TimeBetweenLocalCheckpoints} to 6 or less means that local checkpoints are executed continuously without pause, independent of the cluster's workload.

- \textbf{TimeBetweenGlobalCheckpoints}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>2000</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 32000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart}: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

We recommended when you are using solid-state disks (especially those employing NVMe) with Disk Data tables that you reduce this value. In such cases, you should also ensure that \texttt{MaxDiskDataLatency} is set to a proper level.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- \textbf{TimeBetweenGlobalCheckpointsTimeout}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>120000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart}: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.
• **TimeBetweenEpochs**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

*TimeBetweenEpochs* is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

• **TimeBetweenEpochsTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 256000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

*TimeBetweenEpochsTimeout* is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

• **MaxBufferedEpochs**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>epochs</td>
</tr>
<tr>

<tr>
<td>Range</td>
<td>0 - 100000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a</td>
</tr>
</tbody>
</table>
The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- **MaxBufferedEpochBytes**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>26214400</td>
</tr>
<tr>

<td>(0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong></td>
</tr>
<tr>
<td></td>
<td>Requires a <strong>rolling restart</strong> of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

  The total number of bytes allocated for buffering epochs by this node.

- **TimeBetweenInactiveTransactionAbortCheck**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>1000 - 4294967039</td>
</tr>
<tr>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong></td>
</tr>
<tr>
<td></td>
<td>Requires a <strong>rolling restart</strong> of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

  Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction is checked for timing out once per second.

  The default value is 1000 milliseconds (1 second).
• **TransactionInactiveTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

• **TransactionDeadlockDetectionTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1200</td>
</tr>
<tr>
<td>Range</td>
<td>50 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

• The node is “dead”

• The operation has entered a lock queue
• The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

• **DiskSyncSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>4M</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of `TimeBetweenLocalCheckpoints`.

**Note**

When `ODirect` is enabled, it is not necessary to set `DiskSyncSize`; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

• **MaxDiskWriteSpeed**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>20M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the</td>
</tr>
</tbody>
</table>
Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use `MaxDiskWriteSpeedOwnRestart`. For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

**MaxDiskWriteSpeedOtherNodeRestart**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>50M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use `MaxDiskWriteSpeedOwnRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

**MaxDiskWriteSpeedOwnRestart**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>200M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the</td>
</tr>
</tbody>
</table>
Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- **MinDiskWriteSpeed**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>10M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and `MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

- **ArbitrationTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>7500</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).
**Arbitration**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
<td>Default, Disabled, WaitExternal</td>
</tr>
</tbody>
</table>

**Restart Type**

| Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0) |

The Arbitration parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the ArbitrationRank settings for the management and API nodes. This is the default value.

- **Disabled.** Setting Arbitration = Disabled in the [ndbd default] section of the config.ini file to accomplishes the same task as setting ArbitrationRank to 0 on all management and API nodes. When Arbitration is set in this way, any ArbitrationRank settings are ignored.

- **WaitExternal.** The Arbitration parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by ArbitrationTimeout has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting Arbitration = WaitExternal in the [ndbd default] section of the config.ini file. For best results with the WaitExternal setting, it is recommended that ArbitrationTimeout be 2 times as long as the interval required by the external cluster manager to perform arbitration.

**Important**

This parameter should be used only in the [ndbd default] section of the cluster configuration file. The behavior of the cluster is unspecified when Arbitration is set to different values for individual data nodes.

**RestartSubscriberConnectTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>ms</td>
</tr>
<tr>
<td>Default</td>
<td>12000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type**

| Node Restart: Requires a rolling restart |
This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set `RestartSubscriberConnectTimeout` to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

- **KeepAliveSendInterval**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>60000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

You can enable and control the interval between keep-alive signals sent between data nodes by setting this parameter. The default for `KeepAliveSendInterval` is 60000 milliseconds (one minute); setting it to 0 disables keep-alive signals. Values between 1 and 10 inclusive are treated as 10.

This parameter may prove useful in environments which monitor and disconnect idle TCP connections, possibly causing unnecessary data node failures when the cluster is idle.

The heartbeat interval between management nodes and data nodes is always 100 milliseconds, and is not configurable.

**Buffering and logging.** Several [ndbd] configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s file system abstraction layer.

- **UndoIndexBuffer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter may be useful in environments which monitor and disconnect idle TCP connections, possibly causing unnecessary data node failures when the cluster is idle.
This parameter formerly set the size of the undo index buffer, but has no effect in current versions of NDB Cluster.

Use of this parameter in the cluster configuration file raises a deprecation warning; you should expect it to be removed in a future NDB Cluster release.

• **UndoDataBuffer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 8.0)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter formerly set the size of the undo data buffer, but has no effect in current versions of NDB Cluster.

Use of this parameter in the cluster configuration file raises a deprecation warning; you should expect it to be removed in a future NDB Cluster release.

• **RedoBuffer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the
data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

**RedoBuffer** sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded). For this reason, you should exercise care if you attempt to decrease the value of RedoBuffer as part of an online change in the cluster's configuration.

ndbmtd allocates a separate buffer for each LDM thread (see ThreadConfig). For example, with 4 LDM threads, an ndbmtd data node actually has 4 buffers and allocates RedoBuffer bytes to each one, for a total of 4 * RedoBuffer bytes.

- **EventLogBufferSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>8192</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Controls the size of the circular buffer used for NDB log events within data nodes.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to stdout. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to stdout; setting it to 0 means that no event reports in that category are made.

By default, only the startup message is sent to stdout, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- **LogLevelStartup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>

**LogLevelCongestion**

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

• **LogLevelInfo**

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

• **MemReportFrequency**

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.
This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node’s data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of DataMemory, as set in the config.ini file. For example, if DataMemory is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50% (1280 32K pages of total 2560)
```

MemReportFrequency is not a required parameter. If used, it can be set for all cluster data nodes in the [ndbd default] section of config.ini, and can also be set or overridden for individual data nodes in the corresponding [ndbd] sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 25.6.3.2, “NDB Cluster Log Events”.

Data Node Debugging Parameters

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

- **DictTrace**
It is possible to cause logging of traces for events generated by creating and dropping tables using \textit{DictTrace}. This parameter is useful only in debugging NDB kernel code. \textit{DictTrace} takes an integer value. 0 is the default, and means no logging is performed; 1 enables trace logging, and 2 enables logging of additional DBDICT debugging output.

\begin{itemize}
  \item \textbf{WatchdogImmediateKill}
\end{itemize}

You can cause threads to be killed immediately whenever watchdog issues occur by enabling the \textit{WatchdogImmediateKill} data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

\textbf{Backup parameters.} The \texttt{[ndbd]} parameters discussed in this section define memory buffers set aside for execution of online backups.

\begin{itemize}
  \item \textbf{BackupDataBufferSize}
\end{itemize}
In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum is 512K.

• **BackupDiskWriteSpeedPct**

<table>
<thead>
<tr>

</tbody>
</table>

`BackupDiskWriteSpeedPct` applies only when a backup is single-threaded; since NDB 8.4 supports multi-threaded backups, it is usually not necessary to adjust this parameter, which has no effect in the multi-threaded case. The discussion that follows is specific to single-threaded backups.

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by `MinDiskWriteSpeed` and `MaxDiskWriteSpeed`. Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the `BackupDiskWriteSpeedPct` configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 50 (interpreted as 50%).

• **BackupLogBufferSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>2M - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a</td>
</tr>
</tbody>
</table>
The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 25.6.8.3, “Configuration for NDB Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- **BackupMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.4)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- **BackupReportFrequency**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). BackupReportFrequency represents the time in seconds between backup status reports.

The default value is 0.

• **BackupWriteSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256K</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.6)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

• **BackupMaxWriteSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.6)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.
NDB Cluster Configuration Files

• **CompressedBackup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type**

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.4.0)

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

⚠️ **Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

• **RequireEncryptedBackup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
</tbody>
</table>

**Restart Type**

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.4.0)

If set to 1, backups must be encrypted. While it is possible to set this parameter for each data node individually, it is recommended that you set it in the `[ndbd default]` section of the `config.ini` global configuration file. For more information about performing encrypted backups, see Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”.

⚠️ **Note**

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

**Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node cannot start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`
NDB Cluster Realtime Performance Parameters

The \texttt{ndbd} parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

ewcommand{\NodeRestart}{Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)}

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>BuildIndexThreads</td>
<td></td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 8.4.0</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 128</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\NodeRestart</td>
</tr>
</tbody>
</table>

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running \texttt{ndb_restore --rebuild-indexes}. It is supported only when there is more than one fragment for the table per data node (for example, when \texttt{COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_LDM_X_2"} is used with \texttt{CREATE TABLE}).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using \texttt{ndbd} or \texttt{ndbmtd}.

You can enable multithreaded builds during data node initial restarts by setting the \texttt{TwoPassInitialNodeRestartCopy} data node configuration parameter to \texttt{TRUE}.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LockExecuteThreadToCPU</td>
<td></td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 8.4.0</td>
</tr>
<tr>
<td>Type or units</td>
<td>set of CPU IDs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\NodeRestart</td>
</tr>
</tbody>
</table>

When used with \texttt{ndbd}, this parameter (now a string) specifies the ID of the CPU assigned to handle the \texttt{NDBCLUSTER} execution thread. When used with \texttt{ndbmtd}, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by \texttt{MaxNoOfExecutionThreads}. However, there is no guarantee that threads are assigned to CPUs.
in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- `LockMaintThreadsToCPU`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>CPU ID</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). There is no default value.

- `Numa`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses `ndbd` or `ndbmt`. By default, NDB attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmt`; this is because `ndbmt` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node...
process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set Numa to 0 so that the desired behavior can be determined on the operating system level.

The Numa configuration parameter is supported only on Linux systems where libnuma.so is available.

- **RealtimeScheduler**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

- **SchedulerExecutionTimer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 11000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- **SchedulerResponsiveness**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>5</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 10</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart</td>
</tr>
</tbody>
</table>
Set the balance in the NDB scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- **SchedulerSpinTimer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 500</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

- **Note**

  If SpinMethod is set, any setting for this parameter is ignored.

- **SpinMethod**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>StaticSpinning</td>
</tr>
<tr>
<td>Range</td>
<td>CostBasedSpinning, LatencyOptimisedSpinning, DatabaseMachineSpinning, StaticSpinning</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter provides a simple interface to control adaptive spinning on data nodes, with four possible values furnishing presets for spin parameter values, as shown in the following list:

1. **StaticSpinning** (default): Sets EnableAdaptiveSpinning to false and SchedulerSpinTimer to 0. (SetAllowedSpinOverhead is not relevant in this case.)

2. **CostBasedSpinning**: Sets EnableAdaptiveSpinning to true, SchedulerSpinTimer to 100, and SetAllowedSpinOverhead to 200.

3. **LatencyOptimisedSpinning**: Sets EnableAdaptiveSpinning to true, SchedulerSpinTimer to 200, and SetAllowedSpinOverhead to 1000.
4. **DatabaseMachineSpinning**: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to `500`, and `SetAllowedSpinOverhead` to `10000`. This is intended for use in cases where threads own their own CPUs.

The spin parameters modified by `SpinMethod` are described in the following list:

- **SchedulerSpinTimer**: This is the same as the data node configuration parameter of that name. The setting applied to this parameter by `SpinMethod` overrides any value set in the `config.ini` file.

- **EnableAdaptiveSpinning**: Enables or disables adaptive spinning. Disabling it causes spinning to be performed without making any checks for CPU resources. This parameter cannot be set directly in the cluster configuration file, and under most circumstances should not need to be, but can be enabled directly using `DUMP 104004 1` or disabled with `DUMP 104004 0` in the `ndb_mgm` management client.

- **SetAllowedSpinOverhead**: Sets the amount of CPU time to allow for gaining latency. This parameter cannot be set directly in the `config.ini` file. In most cases, the setting applied by `SpinMethod` should be satisfactory, but if it is necessary to change it directly, you can use `DUMP 104002 overhead` to do so, where `overhead` is a value ranging from `0` to `10000`, inclusive; see the description of the indicated `DUMP` command for details.

On platforms lacking usable spin instructions, such as PowerPC and some SPARC platforms, spin time is set to `0` in all situations, and values for `SpinMethod` other than `StaticSpinning` are ignored.

- **TwoPassInitialNodeRestartCopy**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart</strong>: Requires a <strong>rolling restart</strong> of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `true` (the default value), which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

**Multi-Threading Configuration Parameters (ndbmtd)**. `ndbmtd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. A second method makes it possible to set up more complex rules for `ndbmtd` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

---

**Note**

A backup using parallelism on the data nodes requires that multiple LDMs are in use on all data nodes in the cluster prior to taking the backup. For more
information, see Section 25.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”, as well as Restoring from a backup taken in parallel.

- **AutomaticThreadConfig**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial System Restart:</strong> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When set to 1, enables automatic thread configuration employing the number of CPUs available to a data node taking into account any limits set by `taskset`, `numactl`, virtual machines, Docker, and other such means of controlling which CPUs are available to a given application (on Windows platforms, automatic thread configuration uses all CPUs which are online); alternatively, you can set `NumCPUs` to the desired number of CPUs (up to 1024, the maximum number of CPUs that can be handled by automatic thread configuration). Any settings for `ThreadConfig` and `MaxNoOfExecutionThreads` are ignored. In addition, enabling this parameter automatically disables `ClassicFragmentation`.

- **ClassicFragmentation**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When enabled (set to `true`), NDB distributes fragments among LDMs such that the default number of partitions per node is equal to the minimum number of local data manager (LDM) threads per data node.

For new clusters, setting `ClassicFragmentation` to `false` when first setting up the cluster is preferable; doing so causes the number of partitions per node to be equal to the value of `PartitionsPerNode`, ensuring that all partitions are spread out evenly between all LDMs.

This parameter and `AutomaticThreadConfig` are mutually exclusive; enabling `AutomaticThreadConfig` automatically disables `ClassicFragmentation`.
**EnableMultithreadedBackup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Enables multi-threaded backup. If each data node has at least 2 LDMs, all LDM threads participate in the backup, which is created using one subdirectory per LDM thread, and each subdirectory containing `.ctl`, `.Data`, and `.log` backup files.

This parameter is normally enabled (set to 1) for `ndbmtd`. To force a single-threaded backup that can be restored easily using older versions of `ndb_restore`, disable multi-threaded backup by setting this parameter to 0. This must be done for each data node in the cluster.

See Section 25.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”, and Restoring from a backup taken in parallel, for more information.

**MaxNoOfExecutionThreads**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>2 - 72</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the</td>
</tr>
</tbody>
</table>
This parameter directly controls the number of execution threads used by `ndbmt`, up to a maximum of 72. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmt` and does not apply to `ndbd`.

Enabling AutomaticThreadConfig causes any setting for this parameter to be ignored.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/common/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

**Table 25.11 MaxNoOfExecutionThreads values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).**

<th>Receive Threads</th>
</tr>
</thead>
<tbody>
<tr>
<td>72</td>
<td>32</td>
<td>20</td>
<td>8</td>
<td>10</td>
</tr>
</tbody>
</table>

There is always one SUMA (replication) thread.

NoOfFragmentLogParts should be set equal to the number of LDM threads used by ndbmtdd, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; a configuration in which this is the case is specifically disallowed.

The number of LDM threads also determines the number of partitions used by an NDB table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If ndbd is used on the data nodes rather than ndbmtdd, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes. See Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”, for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the DiskPageBufferMemory configuration parameter, for more information.

The thread types are described later in this section (see ThreadConfig).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error: Error line number: Illegal value value for parameter MaxNoOfExecutionThreads.

For MaxNoOfExecutionThreads, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.

MaxNoOfExecutionThreads is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use ThreadConfig instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a MaxNoOfExecutionThreads value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads normally requires a system restart, whether it is changed using this parameter or ThreadConfig, but it is possible to effect the change using a node initial restart (NI) provided the following two conditions are met:

- Each LDM thread handles a maximum of 8 fragments, and
- The total number of table fragments is an integer multiple of the number of LDM threads.

</tbody>
</table>
This parameter can be used to cause data nodes to wait momentarily before sending data to API nodes; in some circumstances, described in the following paragraphs, this can result in more efficient sending of larger volumes of data and higher overall throughput.

`MaxSendDelay` can be useful when there are a great many API nodes at saturation point or close to it, which can result in waves of increasing and decreasing performance. This occurs when the data nodes are able to send results back to the API nodes relatively quickly, with many small packets to process, which can take longer to process per byte compared to large packets, thus slowing down the API nodes; later, the data nodes start sending larger packets again.

To handle this type of scenario, you can set `MaxSendDelay` to a nonzero value, which helps to ensure that responses are not sent back to the API nodes so quickly. When this is done, responses are sent immediately when there is no other competing traffic, but when there is, setting `MaxSendDelay` causes the data nodes to wait long enough to ensure that they send larger packets. In effect, this introduces an artificial bottleneck into the send process, which can actually improve throughput significantly.

</tr>
</tbody>
</table>

Set the number of log file groups for redo logs belonging to this `ndbmtd`. The value of this parameter should be set equal to the number of LDM threads used by `ndbmtd` as determined by the setting for `MaxNoOfExecutionThreads`. A configuration using more than 4 redo log parts per LDM is disallowed.

See the description of `MaxNoOfExecutionThreads` for more information.

### NumCPUs

<table>
<thead>
<tr>
<th>Version (or later)</th>

</tr>
<tr>
<td>Range</td>
<td>1 - 32</td>
</tr>
</tbody>
</table>

**Restart Type**

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.4.0)

Sets the number of partitions used on each node when creating a new NDB table. This makes it possible to avoid splitting up tables into an excessive number of partitions when the number of local data managers (LDMs) grows high.

While it is possible to set this parameter to different values on different data nodes and there are no known issues with doing so, this is also not likely to be of any advantage; for this reason, it is recommended simply to set it once, for all data nodes, in the `[ndbd default]` section of the global `config.ini` file.

If `ClassicFragmentation` is enabled, any setting for this parameter is ignored. (Remember that enabling `AutomaticThreadConfig` disables `ClassicFragmentation`.)

<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type**

**System Restart:**
NDB Cluster Configuration Files

Requires a complete shutdown and restart of the cluster. (NDB 8.4.0)

This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```plaintext
ThreadConfig := entry[,entry[,...]]
entry := type={param[,param[,...]]}
type := ldm | query | recover | main | recv | send | io | tc | watchdog | idxbld
param := count=number
    | cpubind=cpu_list
    | cpuset=cpu_list
    | spin_time=number
    | realtime={0|1}
    | nosend={0|1}
    | thread_prio={0..10}
    | cpubind_exclusive=cpu_list
    | cpuset_exclusive=cpu_list
```

The curly braces (`{...}`) surrounding the list of parameters are required, even if there is only one parameter in the list.

A `param` (parameter) specifies any or all of the following information:

- The number of threads of the given type (`count`).
- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of `cpubind` or `cpuset`. `cpubind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

  On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. `cpubind_exclusive` causes each thread to be bound exclusively to a CPU in the set; `cpuset_exclusive` means that each thread is bound exclusively to the set of CPUs specified.

  Only one of `cpubind`, `cpuset`, `cpubind_exclusive`, or `cpuset_exclusive` can be provided in a single configuration.

- `spin_time` determines the wait time in microseconds the thread spins before going to sleep.

  The default value for `spin_time` is the value of the `SchedulerSpinTimer` data node configuration parameter.

  `spin_time` does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

  The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

  `realtime` cannot be set for offline index build threads.
• By setting `nosend` to 1, you can prevent a `main`, `ldm`, `rep`, or `tc` thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.

• `thread_prio` is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

The thread priority level cannot be set for offline index build threads.

**thread_prio settings and effects by platform.** The implementation of `thread_prio` differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

• **Linux and FreeBSD:** We map `thread_prio` to a value to be supplied to the `nice` system call. Since a lower niceness value for a process indicates a higher process priority, increasing `thread_prio` has the effect of lowering the `nice` value.

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th><code>nice</code> value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>19</td>
</tr>
<tr>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>6</td>
<td>-4</td>
</tr>
<tr>
<td>7</td>
<td>-8</td>
</tr>
<tr>
<td>8</td>
<td>-12</td>
</tr>
<tr>
<td>9</td>
<td>-16</td>
</tr>
<tr>
<td>10</td>
<td>-20</td>
</tr>
</tbody>
</table>

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum `nice` value that can be set.

• **Solaris:** Setting `thread_prio` on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th>Solaris FX priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>15</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>25</td>
</tr>
<tr>
<td>3</td>
<td>30</td>
</tr>
<tr>
<td>4</td>
<td>35</td>
</tr>
<tr>
<td>5</td>
<td>40</td>
</tr>
<tr>
<td>6</td>
<td>45</td>
</tr>
<tr>
<td>7</td>
<td>50</td>
</tr>
<tr>
<td>8</td>
<td>55</td>
</tr>
</tbody>
</table>
A thread_prio setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- Windows: We map thread_prio to a Windows thread priority value passed to the Windows API SetThreadPriority() function. This mapping is shown in the following table:

<table>
<thead>
<tr>
<th>thread_prio value</th>
<th>Solaris FX priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>59</td>
</tr>
<tr>
<td>10</td>
<td>60</td>
</tr>
</tbody>
</table>

The type attribute represents an NDB thread type. The thread types supported, and the range of permitted count values for each, are provided in the following list:

- ldm: Local query handler (DBLQH kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes.

When ClassicFragmentation is set to 0, the number of partitions is independent of the number of LDM threads, and depends on the value of PartitionsPerNode instead.) Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. ldm can be set to any value in the range 0 to 332 inclusive. When setting it to 0, main, rep, and tc must also be 0, and recv must also be set to 1; doing this causes ndbmtd to emulate ndbd.

Each LDM thread is normally grouped with 1 query thread to form an LDM group. A set of 4 to 8 LDM groups is grouped into a round robin groups. Each LDM thread can be assisted in execution by any query or threads in the same round robin group. NDB attempts to form round robin groups such that all threads in each round robin group are locked to CPUs that are attached to the same L3 cache, within the limits of the range stated for a round robin group's size.

Changing the number of LDM threads normally requires a system restart to be effective and safe for cluster operations; this requirement is relaxed in certain cases, as explained later in this section. This is also true when this is done using MaxNoOfExecutionThreads.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if DiskPageBufferMemory is not sufficiently large.

If ldm is not included in the ThreadConfig value string, one ldm thread is created.

- query: A query thread is tied to an LDM and together with it forms an LDM group; acts only on READ COMMITTED queries. The number of query threads must be set to 0, 1, 2, or 3 times the number of LDM threads. Query threads are not used, unless this is overridden by setting query to a nonzero value, or by enabling the AutomaticThreadConfig parameter.

A query thread also acts as a recovery thread (see next item), although the reverse is not true.

Changing the number of query threads requires a node restart.
• **recover**: A recovery thread restores data from a fragment as part of an LCP.

Changing the number of recovery threads requires a node restart.

• **tc**: Transaction coordinator thread (DBTC kernel block) containing the state of an ongoing transaction. The maximum number of TC threads is 128.

Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

Range: 0-64

• **main**: Data dictionary and transaction coordinator (DBDIH and DBTC kernel blocks), providing schema management. It is also possible to specify zero or two main threads.

Range: 0-2.

Setting `main` to 0 and `rep` to 1 causes the `main` blocks to be placed into the `rep` thread; the combined thread is shown in the `ndbinfo.threads` table as `main_rep`. This is effectively the same as setting `rep` equal to 1 and `main` equal to 0.

It is also possible to set both `main` and `rep` to 0, in which case both threads are placed in the first `recv` thread; the resulting combined thread is named `main_rep_recv` in the `threads` table.

If `main` is omitted from the `ThreadConfig` value string, this, one `main` thread is created.

• **recv**: Receive thread (CMVMI kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

Range: 1 - 64.

If `recv` is omitted from the `ThreadConfig` value string, one `recv` thread is created.

• **send**: Send thread (CMVMI kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

Using an excessive number of send threads can have an adverse effect on scalability.

Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when `MaxNoOfExecutionThreads` is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

Range:

• 0 - 64
NDB Cluster Configuration Files

- **rep**: Replication thread (SUMA kernel block). This thread can also be combined with the main thread (see range information).

  Range: 0-1.

  Setting `rep` to 0 and `main` to 1 causes the `rep` blocks to be placed into the `main` thread; the combined thread is shown in the `ndbinf.threads` table as `main_rep`. This is effectively the same as setting `main` equal to 1 and `rep` equal to 0.

  It is also possible to set both `main` and `rep` to 0, in which case both threads are placed in the first `recv` thread; the resulting combined thread is named `main_rep_recv` in the `threads` table.

  If `rep` is omitted from the `ThreadConfig` value string, one `rep` thread is created.

- **io**: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

  Range: 1 only.

- **watchdog**: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the `SocketServer` thread, which receives connection setups from other nodes; the `SocketClient` thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

  Range: 1 only.

- **idxbld**: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

  The `thread_prio`, `realtime`, and `spintime` values cannot be set for offline index build threads. In addition, `count` is ignored for this type of thread.

  If `idxbld` is not specified, the default behavior is as follows:

  - Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.
  - If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

  Range: 0 - 1.

Changing `ThreadConfig` normally requires a system initial restart, but this requirement can be relaxed under certain circumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or `N`) is required to implement the change.
• Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (NI) provided the following two conditions are met:

a. Each LDM thread handles a maximum of 8 fragments, and

b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

**NDB** can distinguish between thread types by both of the following criteria:

• Whether the thread is an execution thread. Threads of type `main`, `ldm`, `query`, `recv`, `rep`, `tc`, and `send` are execution threads; `io`, `recover`, `watchdog`, and `idxbld` threads are not considered execution threads.

• Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except `idxbld` are considered permanent; `idxbld` threads are regarded as temporary threads.

Simple examples:

```plaintext
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}
# Example 2.
Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```plaintext
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},
rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17},
send={count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.

```plaintext
ThreadConfig=ldm{count=4,cpuset=0-3,thread_prio=8,spintime=200},
ldm{count=4,cpubind=4-7,thread_prio=8,spintime=200},
tc{count=4,cpubind=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11},
main={count=1,cpubind=10},rep={count=1,thread_prio=11}
```

In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the group. (This is not true for `cpubind`.) The send threads use two threads using
**NDB Cluster Configuration Files**

**cpubind** to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how **ThreadConfig** and **NoOfFragmentLogParts** might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```
NoOfFragmentLogParts=10
ThreadConfig=ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200}, \
tc={count=4,cpuset=6-7,18-19,thread_prio=8},send={count=1,cpuset=8}, \
recv={count=1,cpuset=20},main={count=1,cpuset=9,21},rep={count=1,cpuset=9,21}, \
io={count=1,cpuset=9,21,thread_prio=8},watchdog={count=1,cpuset=9,21,thread_prio=9}
```

The next few examples include settings for **idxbld**. The first two of these demonstrate how a CPU set defined for **idxbld** can overlap those specified for other (permanent) thread types, the first using **cpuset** and the second using **cpubind**:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1-8}
ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}
```

The next example specifies a CPU for the I/O thread, but not for the index build threads:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8}
```

Since the **ThreadConfig** setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1,2,3,4,5,6,7,8}
```

In order to take advantage of the enhanced stability that the use of **ThreadConfig** offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting **IRQBALANCE_BANNED_CPUS** in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the **isolcpus** boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- **DiskPageBufferEntries**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64MB</td>
</tr>
<tr>
<td>Range</td>
<td>4MB - 16TB</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in **DiskPageBufferMemory**. The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.
NDB Cluster Configuration Files

- **DiskPageBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 16T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This determines the amount of space, in bytes, used for caching pages on disk, and is set in the [ndbd] or [ndbd default] section of the config.ini file.

If the value for DiskPageBufferMemory is set too low in conjunction with using more than the default number of LDM threads in ThreadConfig (for example {ldm=6...}), problems can arise when trying to add a large (for example 500G) data file to a disk-based NDB table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase DiskPageBufferMemory, or add smaller tablespace files. You may also need to adjust DiskPageBufferEntries.

You can query the ndbinfo.diskpagebuffer table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 25.6.17.31, “The ndbinfo diskpagebuffer Table”, for more information.

- **SharedGlobalMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>128M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the UNDO_BUFFER_SIZE option used with CREATE LOGFILE GROUP and ALTER LOGFILE GROUP statements, including any default value implied for this options by the setting of the InitialLogFileGroup data node configuration parameter. SharedGlobalMemory can be set in the [ndbd] or [ndbd default] section of the config.ini configuration file, and is measured in bytes.

The default value is **128M**.
• **DiskIOThreadPool**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>threads</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter determines the number of unbound threads used for Disk Data file access. Before DiskIOThreadPool was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With DiskIOThreadPool, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can (and should) set DiskIOThreadPool higher to enable separate threads to handle the files on each disk.

You should also disable DiskDataUsingSameDisk when using a separate disk or disks for Disk Data files; this increases the rate at which checkpoints of Disk Data tablespaces can be performed.

- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for DiskIOThreadPool.

Decreasing TimeBetweenGlobalCheckpoints is also recommended when using solid-state disk drives, in particular those using NVMe. See also Disk Data latency parameters.

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.

• **FileSystemPathDD**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPath</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Restart Type</th>
<th>Initial Node Restart:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Requires a rolling restart of the cluster; each data node must be restarted with --initial. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- **FileSystemPathDataFiles**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td><code>FileSystemPathDD</code></td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.
### FileSystemPathUndoFiles

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPathDD</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with (--initial). (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see Section 25.6.11.1, “NDB Cluster Disk Data Objects”.

### Disk Data object creation parameters.

The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- **InitialLogFileGroup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see documentation]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>
  | Restart Type       | System Restart: Requires a complete shutdown and restart of the

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list
```

```
file-specification-list:
  file-specification[; file-specification[; ...]]
```

```
file-specification:
  filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;
```

```
ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory`.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- **InitialTablespace**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see documentation]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System</strong> Restart: Requires a complete shutdown and restart of the</td>
</tr>
</tbody>
</table>
This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. InitialTablespace is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The name of the tablespace is optional and defaults to DEFAULT-TS. The extent_size is also optional; it defaults to 1M. The file-specification-list uses the same syntax as shown with the InitialLogfileGroup parameter, the only difference being that each file-specification used with InitialTablespace corresponds to a data file. At least one must be specified in the file-specification-list. Data files are placed according to any values that have been set for FileSystemPath, FileSystemPathDD, and FileSystemPathDataFiles, just as if they had been created as the result of a CREATE TABLESPACE or ALTER TABLESPACE statement.

For example, consider the following line specifying InitialTablespace in the [ndbd default] section of the config.ini file (as with InitialLogfileGroup, this parameter should always be set in the [ndbd default] section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
    ADD DATAFILE 'data1.dat'
    EXTENT_SIZE 8M
    INITIAL_SIZE 2G
    ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
    ADD DATAFILE 'data2.dat'
    INITIAL_SIZE 4G
    ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with --initial, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

- **Disk Data latency parameters.** The two parameters listed here can be used to improve handling of latency issues with NDB Cluster Disk Data tables.
  - **MaxDiskDataLatency**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>ms</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 8000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter controls the maximum allowed mean latency for disk access (maximum 8000 milliseconds). When this limit is reached, NDB begins to abort transactions in order to decrease pressure on the Disk Data I/O subsystem. Use 0 to disable the latency check.
DiskDataUsingSameDisk

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>
| Restart Type       | Node Restart:
                    Requires a rolling restart
                    of the cluster. (NDB 8.4.0) |

Set this parameter to false if your Disk Data tablespaces use one or more separate disks. Doing so allows checkpoints to tablespaces to be executed at a higher rate than normally used for when disks are shared.

When DiskDataUsingSameDisk is true, NDB decreases the rate of Disk Data checkpointing whenever an in-memory checkpoint is in progress to help ensure that disk load remains constant.

Disk Data and GCP Stop errors. Errors encountered when using Disk Data tables such as Node nodeid killed this node because GCP stop was detected (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of TimeBetweenGlobalCheckpoints tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for DiskPageBufferMemory as explained previously, it is also very important that the DiskIOThreadPool configuration parameter be set correctly; having DiskIOThreadPool set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the TimeBetweenEpochsTimeout data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

Parameters for configuring send buffer memory allocation. Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The TotalSendBufferMemory and OverLoadLimit data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as SendBufferMemory), see Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

ExtraSendBufferMemory

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using TotalSendBufferMemory, SendBufferMemory, or both.

TotalSendBufferMemory

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.
If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

See also Section 25.6.7, “Adding NDB Cluster Data Nodes Online”.

**Redo log over-commit handling.** It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- **RedoOverCommitCounter**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-trying, or aborting them).

- **RedoOverCommitLimit**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its
DefaultOperationRedoProblemAction setting (it either queues the operations to be re-tried, or aborts them).

Controlling restart attempts. It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the MaxStartFailRetries and StartFailRetryDelay data node configuration parameters.

MaxStartFailRetries limits the total number of retries made before giving up on starting the data node, StartFailRetryDelay sets the number of seconds between retry attempts. These parameters are listed here:

- **StartFailRetryDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

  Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

  Both this parameter and MaxStartFailRetries are ignored unless StopOnError is equal to 0.

- **MaxStartFailRetries**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

  Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

  Both this parameter and StartFailRetryDelay are ignored unless StopOnError is equal to 0.

NDB index statistics parameters. The parameters in the following list relate to NDB index statistics generation.

- **IndexStatAutoCreate**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
</table>
Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created.

- **IndexStatAutoUpdate**

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes, and trigger automatic statistics updates when these are detected. The degree of change needed to trigger the updates are determined by the settings for the `IndexStatTriggerPct` and `IndexStatTriggerScale` options.

- **IndexStatSaveSize**
Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the mysqld memory cache.

At least one sample is always produced, regardless of any size limit. This size is scaled by `IndexStatSaveScale`.

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- **IndexStatSaveScale**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with <code>--initial</code> (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- **IndexStatTriggerPct**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with <code>--initial</code> (NDB 8.4.0)</td>
</tr>
</tbody>
</table>
Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

- **IndexStatTriggerScale**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with --initial. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

- **IndexStatUpdateDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with --initial. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:
### Table 25.15 NDB Cluster restart types

</tbody>
</table>

#### 25.4.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

**Note**

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#). For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

- **Id**

<tr>
<td>Restart Type</td>
<td>Initial System Restart: Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

The `Id` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.
Note

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144.

NodeId is the preferred parameter name to use when identifying API nodes. (Id continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- **ConnectionMap**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Specifies which data nodes to connect.

- **NodeId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial System Restart:</strong> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting</td>
</tr>
</tbody>
</table>
The **NodeId** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144.

**NodeId** is the preferred parameter name to use when identifying management nodes. An alias, **Id**, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.5)</td>
</tr>
</tbody>
</table>

This refers to the **Id** set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the **HostName** parameter instead.

- **HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Default</th>
<th>[...]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. Use `HostName` to specify a host name other than `localhost`.

If no `HostName` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. **This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.**

- **LocationDomainId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Assigns an SQL or other API node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use NDB transporters’ WAN support without any further manual intervention.

- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- **ArbitrationRank**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
</table>

3980
This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its ArbitrationRank to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting ArbitrationRank to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the Arbitration parameter in the [ndbd default] section of the config.ini global configuration file.

- **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests are delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- **BatchByteSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16K</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 1M</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in...
terms of number of records (\texttt{BatchSize}) and in terms of bytes (\texttt{BatchByteSize}). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40\% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

- \textbf{BatchSize}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>records</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)}</td>
</tr>
</tbody>
</table>

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- \textbf{ExtraSendBufferMemory}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)}</td>
</tr>
</tbody>
</table>

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using \texttt{TotalSendBufferMemory}, \texttt{SendBufferMemory}, or both.

- \textbf{HeartbeatThreadPriority}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart: Requires a rolling restart}</td>
</tr>
</tbody>
</table>
Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
```

*policy:*
  - FIFO
  - RR

When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first in) or **RR** (round robin). This followed optionally by the priority (an integer).

- **MaxScanBatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256K</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 16M</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- **TotalSendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.
• **AutoReconnect**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.4.0)

This parameter is `false` by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()` and `Ndb_cluster_connection::get_auto_reconnect()`.

• **DefaultOperationRedoProblemAction**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>QUEUE</td>
</tr>
<tr>
<td>Range</td>
<td>ABORT, QUEUE</td>
</tr>
</tbody>
</table>

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.4.0)

This parameter (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) controls the data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of **DefaultOperationRedoProblemAction**, listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.
- **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried.
  This is the default. Pending operations are still aborted when the redo log runs out of space—that is, when `P_TAIL_PROBLEM` errors occur.

• **DefaultHashMapSize**

| Version (or later) | NDB 8.4.0 |
The size of the table hash maps used by NDB is configurable using this parameter. DefaultHashMapSize can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

Table 25.16 DefaultHashMapSize parameter values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Old default hash map size</td>
</tr>
<tr>
<td>3840</td>
<td>Hash map size used by default in NDB 8.4</td>
</tr>
</tbody>
</table>

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible.

- **Wan**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

- **ConnectBackoffMaxTime**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart</td>
</tr>
</tbody>
</table>
In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the `StartConnectBackoffMaxTime` parameter is applied; otherwise, `ConnectBackoffMaxTime` is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed during node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches `ConnectBackoffMaxTime` milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up `HeartbeatIntervalDbApi` for the API node to be notified that this has occurred.

- **StartConnectBackoffMaxTime**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

API Node Debugging Parameters. You can use the `ApiVerbose` configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds `DBDICT` debugging output as well. (Bug #20638450) See also DUMP 1229.
You can also obtain information from a MySQL server running as an NDB Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```sql
mysql> SHOW STATUS LIKE 'ndb%';
+-----------------------------+----------------+
| Variable_name               | Value          |
+-----------------------------+----------------+
| Ndb_cluster_node_id         | 5              |
| Ndb_config_from_host        | 198.51.100.112 |
| Ndb_config_from_port        | 1186           |
| Ndb_number_of_storage_nodes | 4              |
+-----------------------------+----------------+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see NDB Cluster Status Variables.

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

**25.4.3.8 Defining the System**

The `[system]` section is used for parameters applying to the cluster as a whole. The `Name` system parameter is used with MySQL Enterprise Monitor; `ConfigGenerationNumber` and `PrimaryMGMNode` are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, it is not necessary to have a `[system]` section in the `config.ini` file.

More information about these parameters can be found in the following list:

- `ConfigGenerationNumber`
NDB Cluster Configuration Files

Default | 0
---|---
Range | 0 - 4294967039 (0xFFFFFEFF)
Restart Type | **Node Restart**: Requires a rolling restart of the cluster. (NDB 8.4.0)

Configuration generation number. This parameter is currently unused.

- **Name**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.

You can obtain the value of this parameter by checking the `Ndb_system_name` status variable. In NDB API applications, you can also retrieve it using `get_system_name()`.

- **PrimaryMGMNode**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Node ID of the primary management node. This parameter is currently unused.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

### Table 25.18 NDB Cluster restart types

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| N | Node | The parameter can be updated using a rolling restart (see Section 25.6.5, “Performing...
### Symbol | Restart Type | Description
---|---|---
S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I | Initial | Data nodes must be restarted using the `--initial` option

### 25.4.3.9 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see Section 7.1, “The MySQL Server”.

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 25.4, “Configuration of NDB Cluster”.

### MySQL Server Options for NDB Cluster

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see Section 7.1.7, “Server Command Options”.

For information about command-line options used with other NDB Cluster processes, see Section 25.5, “NDB Cluster Programs”.

- **--ndbcluster**

  **Command-Line Format**

  `--ndbcluster [=value]`

  **Disabled by**

  `skip-ndbcluster`

  **Type**

  Enumeration

  **Default Value**

  ON

  **Valid Values**

  OFF

  FORCE

  The NDBCLUSTER storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the NDBCLUSTER storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

  The `--ndbcluster` option is ignored (and the NDB storage engine is not enabled) if `--initialize` is also used. (It is neither necessary nor desirable to use this option together with `--initialize`.)

- **--ndb-allow-copying-alter-table=[ON|OFF]**

  **Command-Line Format**

  `--ndb-allow-copying-alter-table=[ON|OFF]`

  **System Variable**

  `ndb_allow_copying_alter_table`

  **Scope**

  Global, Session

  **Dynamic**

  Yes

  **SET_VAR Hint Applies**

  No

  **Type**

  Boolean
NDB Cluster Configuration Files

Default Value

ON

Let `ALTER TABLE` and other DDL statements use copying operations on NDB tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

• `--ndb-applier-allow-skip-epoch`

Command-Line Format

`--ndb-applier-allow-skip-epoch`

System Variable

`ndb_applier_allow_skip_epoch`

Scope

Global

Dynamic

No

`SET_VAR` Hint Applies

No

Use together with `--replica-skip-errors` to cause NDB to ignore skipped epoch transactions. Has no effect when used alone.

• `--ndb-batch-size=\#`

Command-Line Format

`--ndb-batch-size`

System Variable

`ndb_batch_size`

Scope

Global, Session

Dynamic

Yes

`SET_VAR` Hint Applies

No

Type

Integer

Default Value

32768

Minimum Value

0

Maximum Value

2147483648

Unit

bytes

This sets the size in bytes that is used for NDB transaction batches.

• `--ndb-cluster-connection-pool=\#`

Command-Line Format

`--ndb-cluster-connection-pool`

System Variable

`ndb_cluster_connection_pool`

System Variable

`ndb_cluster_connection_pool`

Scope

Global

Scope

Global

Dynamic

No

Dynamic

`SET_VAR` Hint Applies

No

`SET_VAR` Hint Applies

No

Type

Integer

Default Value

1

Minimum Value

1

Maximum Value

63

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its
own [api] or [mysqld] section in the cluster configuration (config.ini) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose mysqld process was started with --ndb-cluster-connection-pool=4; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running mysqld on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

---

**Important**

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must not use a node ID as part of the cluster connection string when starting any mysqld process that employs connection pooling.

Setting a node ID in the connection string when using the --ndb-cluster-connection-pool option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

---

**--ndb-cluster-connection-pool-nodeids=list**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-cluster-connection-pool-nodeids</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_cluster_connection_pool_nodeids</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>

NDB Cluster Configuration Files

Maximum Value 4294967295

This option can be used to set the size (in bytes) for batching of BLOB data reads in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be read within the current transaction, any pending BLOB read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB read batching.

Note
In NDB API applications, you can control BLOB write batching with the setMaxPendingBlobReadBytes() and getMaxPendingBlobReadBytes() methods.

• --ndb-blob-write-batch-bytes=bytes

Command-Line Format --ndb-blob-write-batch-bytes
System Variable ndb_blob_write_batch_bytes
Scope Global, Session
Dynamic Yes
SET_VAR Hint Applies No
Type Integer
Default Value 65536
Minimum Value 0
Maximum Value 4294967295
Unit bytes

This option can be used to set the size (in bytes) for batching of BLOB data writes in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be written within the current transaction, any pending BLOB write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB write batching.

Note
In NDB API applications, you can control BLOB write batching with the setMaxPendingBlobWriteBytes() and getMaxPendingBlobWriteBytes() methods.

• --ndb-connectstring=connection_string

Command-Line Format --ndb-connectstring
Type String

When using the NDBCLUSTER storage engine, this option specifies the management server that distributes cluster configuration data. See Section 25.4.3.3, “NDB Cluster Connection Strings”, for syntax.

• --ndb-default-column-format=[FIXED|DYNAMIC]

Command-Line Format --ndb-default-column-format=[FIXED|DYNAMIC]
System Variable ndb_default_column_format
Sets the default COLUMN_FORMAT and ROW_FORMAT for new tables (see Section 15.1.20, “CREATE TABLE Statement”). The default is FIXED.

- **--ndb-deferred-constraints=[0|1]**

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. 0 is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- **--ndb-schema-dist-timeout=#**

Specifies the maximum time in seconds that this mysqld waits for a schema operation to complete before marking it as having timed out.

- **--ndb-distribution=[KEYHASH|LINHASH]**

<table>

<th>FIXED, DYNAMIC</th>
</tr>
</thead>
</table>

Sets the default COLUMN_FORMAT and ROW_FORMAT for new tables (see Section 15.1.20, “CREATE TABLE Statement”). The default is FIXED.

- **--ndb-deferred-constraints=[0|1]**

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. 0 is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- **--ndb-schema-dist-timeout=#**

Specifies the maximum time in seconds that this mysqld waits for a schema operation to complete before marking it as having timed out.

- **--ndb-distribution=[KEYHASH|LINHASH]**

<td>LINHASH</td>
</tr>
</tbody>
</table>

Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

• **--ndb-log-apply-status**

| Command-Line Format | --ndb-log-apply-status={OFF|ON} |
|---------------------|---------------------------------|
| System Variable     | ndb_log_apply_status            |
| Scope               | Global                          |
| Dynamic             | No                              |
| SET_VAR Hint Applies| No                              |
| Type                | Boolean                         |
| Default Value       | OFF                             |

Causes a replica mysqld to log any updates received from its immediate source to the mysql.ndb_apply_status table in its own binary log using its own server ID rather than the server ID of the source. In a circular or chain replication setting, this allows such updates to propagate to the mysql.ndb_apply_status tables of any MySQL servers configured as replicas of the current mysqld.

In a chain replication setup, using this option allows downstream (replica) clusters to be aware of their positions relative to all of their upstream contributors (sources).

In a circular replication setup, this option causes changes to ndb_apply_status tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a replication source to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the **--ndbcluster** option.

• **--ndb-log-empty-epochs=[ON|OFF]**

| Command-Line Format | --ndb-log-empty-epochs={OFF|ON} |
|---------------------|---------------------------------|
| System Variable     | ndb_log_empty_epochs            |
| Scope               | Global                          |
| Dynamic             | Yes                             |
| SET_VAR Hint Applies| No                              |
| Type                | Boolean                         |
NDB Cluster Configuration Files

Default Value

OFF

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

• `--ndb-log-empty-update=\{ON\|OFF\}`

Command-Line Format

`--ndb-log-empty-update[=\{OFF\|ON\}]`

System Variable

`ndb_log_empty_update`

Scope

Global

Dynamic

Yes

SET_VAR Hint Applies

No

Type

Boolean

Default Value

OFF

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` is enabled.

By default this option is disabled (OFF). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

• `--ndb-log-exclusive-reads=\{0\|1\}`

Command-Line Format

`--ndb-log-exclusive-reads[=\{OFF\|ON\}]`

System Variable

`ndb_log_exclusive_reads`

Scope

Global, Session

Dynamic

Yes

SET_VAR Hint Applies

No

Type

Boolean

Default Value

0

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see Read conflict detection and resolution.

• `--ndb-log-fail-terminate`

Command-Line Format

`--ndb-log-fail-terminate`

System Variable

`ndb_log_fail_terminate`

Scope

Global

Dynamic

No

SET_VAR Hint Applies

No

Type

Boolean

Default Value

0

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see Read conflict detection and resolution.
When this option is specified, and complete logging of all found row events is not possible, the \texttt{mysqld} process is terminated.

- \texttt{--ndb-log-orig}

\begin{itemize}
  \item Command-Line Format: \texttt{--ndb-log-orig[={OFF|ON}]}  
  \item System Variable: \texttt{ndb_log_orig}  
  \item Scope: Global  
  \item Dynamic: No  
  \item \texttt{SET_VAR} Hint Applies: No  
  \item Type: Boolean  
  \item Default Value: \texttt{OFF}  
\end{itemize}

Log the originating server ID and epoch in the \texttt{ndb_binlog_index} table.

\textbf{Note}  
This makes it possible for a given epoch to have multiple rows in \texttt{ndb_binlog_index}, one for each originating epoch.

For more information, see Section 25.7.4, “NDB Cluster Replication Schema and Tables”.

- \texttt{--ndb-log-transaction-dependency}

\begin{itemize}
  \item Command-Line Format: \texttt{--ndb-log-transaction-dependency={true|false}}  
  \item System Variable: \texttt{ndb_log_transaction_dependency}  
  \item Scope: Global  
  \item Dynamic: No  
  \item \texttt{SET_VAR} Hint Applies: No  
  \item Type: Boolean  
  \item Default Value: \texttt{false}  
\end{itemize}

Causes the NDB binary logging thread to calculate transaction dependencies for each transaction which it writes to the binary log. The default value is \texttt{FALSE}.

This option cannot be set at runtime; the corresponding \texttt{ndb_log_transaction_dependency} system variable is read-only.

- \texttt{--ndb-log-transaction-id}

\begin{itemize}
  \item Command-Line Format: \texttt{--ndb-log-transaction-id[={OFF|ON}]}  
  \item System Variable: \texttt{ndb_log_transaction_id}  
  \item Scope: Global  
  \item Dynamic: No  
  \item \texttt{SET_VAR} Hint Applies: No  
  \item Type: Boolean  
\end{itemize}
NDB Cluster Configuration Files

Default Value | OFF
---|---

Causes a replica mysqld to write the NDB transaction ID in each row of the binary log. The default value is FALSE.

--ndb-log-transaction-id is required to enable NDB Cluster Replication conflict detection and resolution using the NDB$EPOCH_TRANS() function (see NDB$EPOCH_TRANS()). For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• --ndb-log-update-as-write

Command-Line Format | --ndb-log-update-as-write={OFF|ON}
System Variable | ndb_log_update_as_write
Scope | Global
Dynamic | Yes
SET_VAR Hint Applies | No
Type | Boolean
Default Value | ON

Whether updates on the source are written to the binary log as updates (OFF) or writes (ON). When this option is enabled, and both --ndb-log-updated-only and --ndb-log-update-minimal are disabled, operations of different types are logged as described in the following list:

• INSERT: Logged as a WRITE_ROW event with no before image; the after image is logged with all columns.

• UPDATE: Logged as a WRITE_ROW event with no before image; the after image is logged with all columns.

• DELETE: Logged as a DELETE_ROW event with all columns logged in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see ndb_replication Table, for more information.

• --ndb-log-updated-only

Command-Line Format | --ndb-log-updated-only={OFF|ON}
System Variable | ndb_log_updated_only
Scope | Global
Dynamic | Yes
SET_VAR Hint Applies | No
Type | Boolean
Default Value | ON

Whether mysqld writes updates only (ON) or complete rows (OFF) to the binary log. When this option is enabled, and both --ndb-log-update-as-write and --ndb-log-update-minimal are disabled, operations of different types are logged as described in the following list:

• INSERT: Logged as a WRITE_ROW event with no before image; the after image is logged with all columns.

• UPDATE: Logged as an UPDATE_ROW event with primary key columns and updated columns present in both the before and after images.
• **DELETE**: Logged as a **DELETE_ROW** event with primary key columns included in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see `ndb_replication Table`, for more information about how these options interact with one another.

• **--ndb-log-update-minimal**

| Command-Line Format | --ndb-log-update-minimal[={OFF|ON}] |
|---------------------|-------------------------------------|
| System Variable     | ndb_log_update_minimal               |
| Scope               | Global                              |
| Dynamic             | Yes                                 |
| **SET_VAR** Hint Applies | No                               |
| Type                | Boolean                             |
| Default Value       | OFF                                 |

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than **NDB**. When this option is enabled, and both **--ndb-log-updated-only** and **--ndb-log-update-as-write** are disabled, operations of different types are logged as described in the following list:

• **INSERT**: Logged as a **WRITE_ROW** event with no before image; the after image is logged with all columns.

• **UPDATE**: Logged as an **UPDATE_ROW** event with primary key columns in the before image; all columns except primary key columns are logged in the after image.

• **DELETE**: Logged as a **DELETE_ROW** event with all columns in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see `ndb_replication Table`, for more information.

• **--ndb-mgm-tls=[relaxed|strict]**

| Command-Line Format | --ndb-mgm-tls=[strict|relaxed] |
|---------------------|---------------------------------|
| System Variable     | ndb_mgm_tls                     |
| Scope               | Global                          |
| Dynamic             | No                              |
| **SET_VAR** Hint Applies | No                           |
| Type                | Enumeration                     |
| Default Value       | relaxed                         |
| Valid Values        | relaxed                         |
|                     | strict                           |

Sets the level of TLS support required for TLS connections to NDB Cluster; the value is one of **relaxed** or **strict**. **relaxed** means that a TLS connection is attempted, but success is not required; **strict** means that TLS is required to connect. The default is **relaxed**.
NDB Cluster Configuration Files

• **--ndb-mgmd-host=host[:port]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-mgmd-host=host_name[:port_num]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

  Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the **--ndb-connectstring** option instead.

• **--ndb-nodeid=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodeid=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status Variable</td>
<td>Ndb_cluster_node_id</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>N/A</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>63</td>
</tr>
</tbody>
</table>

  Set this MySQL server's node ID in an NDB Cluster.

  The **--ndb-nodeid** option overrides any node ID set with **--ndb-connectstring**, regardless of the order in which the two options are used.

  In addition, if **--ndb-nodeid** is used, then either a matching node ID must be found in a [mysqld] or [api] section of config.ini, or there must be an “open” [mysqld] or [api] section in the file (that is, a section without a NodeId or Id parameter specified). This is also true if the node ID is specified as part of the connection string.

  Regardless of how the node ID is determined, it is shown as the value of the global status variable Ndb_cluster_node_id in the output of **SHOW STATUS**, and as cluster_node_id in the connection row of the output of **SHOW ENGINE NDBCLUSTER STATUS**.

  For more information about node IDs for NDB Cluster SQL nodes, see Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

• **--ndbinfo={ON|OFF|FORCE}**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndbinfo={value}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE</td>
</tr>
</tbody>
</table>

  Enables the plugin for the ndbinfo information database. By default this is ON whenever NDBCLUSTER is enabled.
### --ndb-optimization-delay=milliseconds

**Command-Line Format**

```
--ndb-optimization-delay=#
```

**System Variable**

`ndb_optimization_delay`

**Scope**

Global

**Dynamic**

Yes

**SET_VAR Hint Applies**

No

**Type**

Integer

**Default Value**

10

**Minimum Value**

0

**Maximum Value**

100000

**Unit**

milliseconds

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on NDB tables. The default is 10.

### --ndb-optimized-node-selection

**Command-Line Format**

```
--ndb-optimized-node-selection
```

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

### ndb-tls-search-path=path

**Command-Line Format**

```
--ndb-tls-search-path=path
```

**System Variable**

`ndb_tls_search_path`

**Scope**

Global

**Dynamic**

No

**SET_VAR Hint Applies**

No

**Type**

Path name

**Default Value (Unix)**

`$HOME/tls`

**Default Value (Windows)**

`$HOMEDIR/tls`

List of directories to search for CAs and private keys for NDB TLS connections. The list is comma-delimited on Unix platforms and semicolon-delimited on Windows.

### --ndb-transid-mysql-connection-map=state

**Command-Line Format**

```
--ndb-transid-mysql-connection-map[=state]
```

**Type**

Enumeration

**Default Value**

`ON`

**Valid Values**

`ON`, `OFF`, `FORCE`

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes
**ndb_transid_mysql_connection_map** inaccessible. **FORCE** keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the **ndb_transid_mysql_connection_map** table plugin is running by checking the output of **SHOW PLUGINS**.

- **--ndb-wait-connected=seconds**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-wait-connected=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_wait_connected</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>120</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is **30**.

- **--ndb-wait-setup=seconds**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-wait-setup=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_wait_setup</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>120</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Default Value</td>
<td>15</td>
</tr>
<tr>
<td>Default Value</td>
<td>15</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds. The default value is **30**.

- **--skip-ndbcluster**

Disable the **NDBCLUSTER** storage engine. This is the default for binaries that were built with **NDBCLUSTER** storage engine support; the server allocates memory and other resources for this...
storage engine only if the `--ndbcluster` option is given explicitly. See Section 25.4.1, “Quick Test Setup of NDB Cluster”, for an example.

**NDB Cluster System Variables**

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the NDB storage engine. For system variables not specific to NDB Cluster, see Section 7.1.8, “Server System Variables”. For general information on using system variables, see Section 7.1.9, “Using System Variables”.

- **ndb_autoincrement_prefetch_sz**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-autoincrement-prefetch-sz=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_autoincrement_prefetch_sz</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>512</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65536</td>
</tr>
</tbody>
</table>

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood of consecutive autoincrement numbers being used in a batch of inserts.

This variable affects only the number of `AUTO_INCREMENT` IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time.

⚠️ **Important**

This variable does not affect inserts performed using `INSERT ... SELECT`.

- **ndb_clear_apply_status**

  | Command-Line Format | `--ndb-clear-apply-status[{OFF|ON}]` |
  |---------------------|-------------------------------------|
  | System Variable     | `ndb_clear_apply_status`             |
  | Scope               | Global                              |
  | Dynamic             | Yes                                 |
  | `SET_VAR` Hint Applies | No                               |
  | Type                | Boolean                             |
  | Default Value       | `ON`                                |

By the default, executing `RESET REPLICA` causes an NDB Cluster replica to purge all rows from its `ndb_apply_status` table. You can disable this by setting `ndb_clear_apply_status=OFF`.

- **ndb_conflict_role**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-conflict-role=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_conflict_role</code></td>
</tr>
<tr>
<td>Scope</td>

**ndb_conflict_role**

<table>
<thead>
<tr>
<th>Set_VAR</th>
<th>Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>Valid Values</td>
<td>PRIMARY, SECONDARY, PASS</td>
<td></td>
</tr>
</tbody>
</table>

Determines the role of this SQL node (and NDB Cluster) in a circular (“active-active”) replication setup. *ndb_conflict_role* can take any one of the values PRIMARY, SECONDARY, PASS, or NULL (the default). The replica SQL thread must be stopped before you can change *ndb_conflict_role*. In addition, it is not possible to change directly between PASS and either of PRIMARY or SECONDARY directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_conflict_role = 'NONE'` first.

This variable replaces the deprecated *ndb_slave_conflict_role*.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **ndb_data_node_neighbour**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-data-node-neighbour=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_data_node_neighbour</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Set_VAR Hint Applies</td>

</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

See Section 15.1.20.12, “Setting NDB Comment Options”, for further information.

**Note**

An equivalent method *set_data_node_neighbour()* is provided for use in NDB API applications.

• **ndb_dbg_check_shares**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-dbgl-check-shares=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_dbg_check_shares</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

When set to 1, check that no shares are lingering. Available in debug builds only.

- **ndb_default_column_format**

  Command-Line Format  
  --ndb-default-column-format={FIXED|DYNAMIC}

  System Variable  
  ndb_default_column_format

  Scope  
  Global

  Dynamic  
  Yes

  **SET_VAR** Hint Applies  
  No

  **Type**  
  Enumeration

  Default Value  
  FIXED

  Valid Values  
  FIXED

  DYNAMIC

Sets the default COLUMN_FORMAT and ROW_FORMAT for new tables (see Section 15.1.20, "CREATE TABLE Statement"). The default is FIXED.

- **ndb_deferred_constraints**

  Command-Line Format  
  --ndb-deferred-constraints=#

  System Variable  
  ndb_deferred_constraints

  Scope  
  Global, Session

  Dynamic  
  Yes

  **SET_VAR** Hint Applies  
  No

  **Type**  
  Integer

  Default Value  
  0

  Minimum Value  
  0

  Maximum Value  
  1

Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- **ndb_distribution**

  Command-Line Format  
  --ndb-distribution={KEYHASH|LINHASH}

  System Variable  
  ndb_distribution

  Scope  
  Global

  **Type**  
  Integer

  Default Value  
  0

  Minimum Value  
  0

  Maximum Value  
  1
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>KEYHASH</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td>LINHASH, KEYHASH</td>
</tr>
</tbody>
</table>

Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

**ndb_eventbuffer_free_percent**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-eventbuffer-free-percent=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td>ndb_eventbuffer_free_percent</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>20</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>99</td>
</tr>
</tbody>
</table>

Sets the percentage of the maximum memory allocated to the event buffer (ndb_eventbuffer_max_alloc) that should be available in event buffer after reaching the maximum, before starting to buffer again.

**ndb_eventbuffer_max_alloc**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-eventbuffer-max-alloc=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td>ndb_eventbuffer_max_alloc</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>922372036854775807</td>
</tr>
</tbody>
</table>

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

**ndb_extra_logging**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>ndb_extra_logging=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td>ndb_extra_logging</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it is set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

• ndb_force_send

Command-Line Format  --ndb-force-send=[{OFF|ON}]
System Variable      ndb_force_send
Scope                Global, Session
Dynamic              Yes
SET_VAR Hint Applies No
Type                 Boolean
Default Value        ON

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

• ndb_fully_replicated

Command-Line Format  --ndb-fully-replicated=[{OFF|ON}]
System Variable      ndb_fully_replicated
Scope                Global, Session
Dynamic              Yes
SET_VAR Hint Applies No
Type                 Boolean
Default Value        OFF

Determines whether new NDB tables are fully replicated. This setting can be overridden for an individual table using COMMENT="NDB_TABLE=FULLY_REPLICATED=..." in a CREATE TABLE or ALTER TABLE statement; see Section 15.1.20.12, “Setting NDB Comment Options”, for syntax and other information.

• ndb_index_stat_enable

Command-Line Format  --ndb-index-stat-enable=[{OFF|ON}]
System Variable      ndb_index_stat_enable
Scope                Global, Session
Dynamic              Yes
SET_VAR Hint Applies No
Type                 Boolean
Use NDB index statistics in query optimization. The default is ON.

The index statistics tables are always created when the server starts, regardless of this option's value.

- **ndb_index_stat_option**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-index-stat-option=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_index_stat_option</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>loop_checkon=1000ms,loop_idle=1000ms,loop_busy=100ms,update_batch=1,read_batch=4,idle_batch=32,check_delay=1m,delete_batch=8,clean_delay=0,error_delay=1m,evict_batch=8,evict_delay=1m,cache_limit=32M,cache_lowpct=90</td>
</tr>
</tbody>
</table>

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting ndb_index_stat_option are not changed from their default values. For example, you can set ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'.

Time values can be optionally suffixed with h (hours), m (minutes), or s (seconds). Millisecond values can optionally be specified using ms; millisecond values cannot be specified using h, m, or s. Integer values can be suffixed with K, M, or G.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

**ndb_join_pushdown**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_join_pushdown</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable controls whether joins on NDB tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of NDB by the SQL node; however, when ndb_join_pushdown is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to mysqld. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, ndb_join_pushdown is enabled.

**Conditions for NDB pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use exactly the same data type. This means that (for example) a join on an INT column and a BIGINT column also cannot be pushed down.

Expressions comparing columns from the same table can also be pushed down. The columns (or the result of any operations on those columns) must be of exactly the same type, including
the same signedness, length, character set and collation, precision, and scale, where these are applicable.

2. Queries referencing BLOB or TEXT columns are not supported.

3. Explicit locking is not supported; however, the NDB storage engine’s characteristic implicit row-based locking is enforced.

   This means that a join using FOR UPDATE cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the ref, eq_ref, or const access methods, or some combination of these methods.

   Outer joined child tables can only be pushed using eq_ref.

   If the root of the pushed join is an eq_ref or const, only child tables joined by eq_ref can be appended. (A table joined by ref is likely to become the root of another pushed join.)

   If the query optimizer decides on Using join cache for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by [LINEAR] HASH, LIST, or RANGE currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with EXPLAIN; when the join can be pushed down, you can see references to the pushed join in the Extra column of the output, as shown in this example:

```sql
mysql> EXPLAIN
    -> SELECT e.first_name, e.last_name, t.title, d.dept_name
    -> FROM employees e
    -> JOIN dept_emp de ON e.emp_no=de.emp_no
    -> JOIN departments d ON d.dept_no=de.dept_no
    -> JOIN titles t ON e.emp_no=t.emp_no

*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: d
    type: ALL
  possible_keys: PRIMARY
    key: NULL
    key_len: NULL
    ref: NULL
    rows: 9
  Extra: Parent of 4 pushed join@1

*************************** 2. row ***************************
  id: 1
  select_type: SIMPLE
  table: de
    type: ref
  possible_keys: PRIMARY,emp_no,dept_no
    key: dept_no
    key_len: 4
    ref: employees.d.dept_no
    rows: 5305
  Extra: Child of 'd' in pushed join@1

*************************** 3. row ***************************
  id: 1
  select_type: SIMPLE
  table: e
    type: eq_ref
  possible_keys: PRIMARY
    key: PRIMARY
    key_len: 4
    ref: employees.de.emp_no
    rows: 1
  Extra: Child of 'de' in pushed join@1
```
Note

If inner joined child tables are joined by **ref**, and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.

2. The counters in the `ndbinfo.counters` table that belong to the DBSPJ kernel block.

   - **ndb_log_apply_status**

     | Command-Line Format | --ndb-log-apply-status[={OFF|ON}] |
     |---------------------|-----------------------------------|
     | System Variable     | `ndb_log_apply_status`            |
     | Scope               | Global                            |
     | Dynamic             | No                                |
     | SET_VAR Hint Applies| No                                |
     | Type                | Boolean                           |
     | Default Value       | OFF                               |

   A read-only variable which shows whether the server was started with the **--ndb-log-apply-status** option.

   - **ndb_log_bin**

     | Command-Line Format | --ndb-log-bin[={OFF|ON}] |
     |---------------------|--------------------------|
     | System Variable     | `ndb_log_bin`            |
     | Scope               | Global, Session          |
     | Dynamic             | No                       |
     | SET_VAR Hint Applies| No                       |
     | Type                | Boolean                  |
     | Default Value       | OFF                      |

   Causes updates to NDB tables to be written to the binary log. The setting for this variable has no effect if binary logging is not already enabled on the server using `log_bin.ndb_log_bin` defaults to 0 (FALSE).

   - **ndb_log_binlog_index**

     | Command-Line Format | --ndb-log-binlog-index[={OFF|ON}] |
     |---------------------|-----------------------------------|
     | System Variable     | `ndb_log_binlog_index`            |
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Variable</th>
<th>Command-Line Format</th>
<th>System Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>SET_VAR Hint Applies</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ndb_log_empty_epochs</td>
<td>`--ndb-log-empty-epochs[={OFF</td>
<td>ON}]`</td>
<td><code>ndb_log_empty_epochs</code></td>
<td>Global</td>
<td>Yes</td>
<td>No</td>
<td>Boolean</td>
</tr>
<tr>
<td>ndb_log_empty_update</td>
<td>`--ndb-log-empty-update[={OFF</td>
<td>ON}]`</td>
<td><code>ndb_log_empty_update</code></td>
<td>Global</td>
<td>Yes</td>
<td>No</td>
<td>Boolean</td>
</tr>
<tr>
<td>ndb_log_exclusive_reads</td>
<td>`--ndb-log-exclusive-reads[={OFF</td>
<td>ON}]`</td>
<td><code>ndb_log_exclusive_reads</code></td>
<td>Global, Session</td>
<td>Yes</td>
<td>No</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

**ndb_log_binlog_index**

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.)

*ndb_log_binlog_index* defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

**ndb_log_empty_epochs**

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

**ndb_log_empty_update**

When this variable is set to ON (1), update transactions with no changes are written to the binary log, even when `log_replica_updates` is enabled.

**ndb_log_exclusive_reads**

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these features:

```
set var ndb_log_exclusive_reads ON;
```
locks, set the value of `ndb_log_exclusive_reads` to 1.0, which disables such locking, is the default.

For more information, see Read conflict detection and resolution.

- **ndb_log_orig**

  Command-Line Format
  
  --ndb-log-orig=[{OFF|ON}]

  System Variable
  
  `ndb_log_orig`

  Scope
  
  Global

  Dynamic
  
  No

  SET_VAR Hint Applies
  
  No

  Type
  
  Boolean

  Default Value
  
  OFF

  Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- **ndb_log_transaction_id**

  System Variable
  
  `ndb_log_transaction_id`

  Scope
  
  Global

  Dynamic
  
  No

  SET_VAR Hint Applies
  
  No

  Type
  
  Boolean

  Default Value
  
  OFF

  This read-only, Boolean system variable shows whether a replica `mysqld` writes NDB transaction IDs in the binary log (required to use "active-active" NDB Cluster Replication with NDB $EPOCH_TRANS() conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

  `ndb_log_transaction_id` is not supported in mainline MySQL Server 8.4.

  For more information, see Section 25.7.12, "NDB Cluster Replication Conflict Resolution".

- **ndb_log_transaction_compression**

  Command-Line Format
  
  --ndb-log-transaction-compression

  System Variable
  
  `ndb_log_transaction_compression`

  Scope
  
  Global

  Dynamic
  
  Yes

  SET_VAR Hint Applies
  
  No

  Type
  
  Boolean
NDB Cluster Configuration Files

**Default Value**

| OFF |

Whether a replica *mysqld* writes compressed transactions in the binary log; present only if *mysqld* was compiled with support for NDB.

You should note that starting the MySQL server with `--binlog-transaction-compression` forces this variable to be enabled (ON), and that this overrides any setting for `--ndb-log-transaction-compression` made on the command line or in a `my.cnf` file, as shown here:

```
$> mysqld_safe --ndbcluster --ndb-connectstring=127.0.0.1
   --binlog-transaction-compression=ON --ndb-log-transaction-compression=OFF &
[1] 27667
$> 2022-07-07T12:29:29.459937Z mysqld_safe Logging to '/usr/local/mysql/data/myhost.err'.
2022-07-07T12:29:29.509873Z mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/data
$> mysql -e 'SHOW VARIABLES LIKE "%transaction_compression\%"'
+--------------------------------------------+-------+
| Variable_name                              | Value |
+--------------------------------------------+-------+
| binlog_transaction_compression             | ON    |
| binlog_transaction_compression_level_zstd  | 3     |
| ndb_log_transaction_compression            | ON    |
| ndb_log_transaction_compression_level_zstd | 3     |
+--------------------------------------------+-------+
```

To disable binary log transaction compression for NDB tables only, set the `ndb_log_transaction_compression` system variable to OFF in a `mysql` or other client session after starting `mysqld`.

Setting the `binlog_transaction_compression` variable after startup has no effect on the value of `ndb_log_transaction_compression`.

For more information on binary log transaction compression, such as which events are or are not compressed and as well as behavior changes to be aware of when this feature is used, see Section 7.4.4.5, "Binary Log Transaction Compression".

- **ndb_log_transaction_compression_level_zstd**

  **Command-Line Format**

  `--ndb-log-transaction-compression-level-zstd=#`

  **System Variable**

  `ndb_log_transaction_compression_level_zstd`

  **Scope**

  Global

  **Dynamic**

  Yes

  **SET_VAR**

  Hint Applies

  No

  **Type**

  Integer

  **Default Value**

  3

  **Minimum Value**

  1

  **Maximum Value**

  22

  The ZSTD compression level used for writing compressed transactions to the replica's binary log if enabled by `ndb_log_transaction_compression`. Not supported if `mysqld` was not compiled with support for the NDB storage engine.

  See Section 7.4.4.5, "Binary Log Transaction Compression", for more information.

- **ndb_metadata_check**

  **Command-Line Format**

  `--ndb-metadata-check=[]`
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_metadata_check</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

NDB uses a background thread to check for metadata changes each \( \text{ndb_metadata_check_interval} \) seconds as compared with the MySQL data dictionary. This metadata change detection thread can be disabled by setting \( \text{ndb_metadata_check} \) to OFF. The thread is enabled by default.

- \( \text{ndb_metadata_check_interval} \)

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-metadata-check-interval=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_metadata_check_interval</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

NDB runs a metadata change detection thread in the background to determine when the NDB dictionary has changed with respect to the MySQL data dictionary. By default, the interval between such checks is 60 seconds; this can be adjusted by setting the value of \( \text{ndb_metadata_check_interval} \). To enable or disable the thread, use \( \text{ndb_metadata_check} \).

- \( \text{ndb_metadata_sync} \)

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_metadata_sync</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Setting this variable causes the change monitor thread to override any values set for \( \text{ndb_metadata_check} \) or \( \text{ndb_metadata_check_interval} \), and to enter a period of continuous change detection. When the thread ascertains that there are no more changes to be detected, it stalls until the binary logging thread has finished synchronization of all detected objects. \( \text{ndb_metadata_sync} \) is then set to false, and the change monitor thread reverts to the behavior determined by the settings for \( \text{ndb_metadata_check} \) and \( \text{ndb_metadata_check_interval} \).

Setting this variable to true causes the list of excluded objects to be cleared; setting it to false clears the list of objects to be retried.
NDB Cluster Configuration Files

- **ndb_optimized_node_selection**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-optimized-node-selection=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_optimized_node_selection</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3</td>
</tr>
</tbody>
</table>

There are two forms of optimized node selection, described here:

1. The SQL node uses **proximity** to determine the transaction coordinator; that is, the "closest" data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be "closest" to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to **localhost**, followed by TCP connection from a host other than **localhost**.

2. The SQL thread uses **distribution awareness** to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

- 0: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
- 1: Proximity to the SQL node is used to determine the transaction coordinator.
- 2: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.
- 3: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the **Group** parameter (default 55).
2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for **Group**, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.
3. Setting **ndb_data_node_neighbour** further decreases the effective **Group** value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in **ndb_data_node_neighbour** are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.
• ndb_read_backup

| Command-Line Format | --ndb-read-backup=[{OFF|ON}] |
|---------------------|-----------------------------|
| System Variable     | ndb_read_backup             |
| Scope               | Global                      |
| Dynamic             | Yes                         |
| SET_VAR Hint Applies| No                          |
| Type                | Boolean                     |
| Default Value       | ON                          |

Enable read from any fragment replica for any NDB table subsequently created; doing so greatly improves the table read performance at a relatively small cost to writes.

If the SQL node and the data node use the same host name or IP address, this fact is detected automatically, so that the preference is to send reads to the same host. If these nodes are on the same host but use different IP addresses, you can tell the SQL node to use the correct data node by setting the value of ndb_data_node_neighbour on the SQL node to the node ID of the data node.

To enable or disable read from any fragment replica for an individual table, you can set the NDB_TABLE option READ_BACKUP for the table accordingly, in a CREATE TABLE or ALTER TABLE statement; see Section 15.1.20.12, “Setting NDB Comment Options”, for more information.

• ndb_recv_thread_activation_threshold

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-recv-thread-activation-threshold=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_recv_thread_activation_threshold</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0 (MIN_ACTIVATION_THRESHOLD)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16 (MAX_ACTIVATION_THRESHOLD)</td>
</tr>
</tbody>
</table>

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set at startup.

• ndb_recv_thread_cpu_mask

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-recv-thread-cpu-mask=mask</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_recv_thread_cpu_mask</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Bitmap</td>
</tr>
</tbody>
</table>
### CPU mask for locking receiver threads to specific CPUs

This is specified as a hexadecimal bitmask. For example, `0x33` means that one CPU is used per receiver thread. An empty string is the default; setting `ndb_recv_thread_cpu_mask` to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set at startup.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ndb_recv_thread_cpu_mask</code></td>
<td>CPU mask for locking receiver threads to specific CPUs.</td>
</tr>
<tr>
<td>Default Value</td>
<td>[empty]</td>
</tr>
</tbody>
</table>

### `ndb_report_thresh_binlog_epoch_slip`

- **Command-Line Format**: `--ndb-report-thresh-binlog-epoch-slip=#`
- **System Variable**: `ndb_report_thresh_binlog_epoch_slip`
- **Scope**: Global
- **Dynamic**: Yes
- **SET_VAR Hint Applies**: No
- **Type**: Integer
- **Default Value**: 10
- **Minimum Value**: 0
- **Maximum Value**: 256

This represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with `BUFFERED_EPOCHS_OVER_THRESHOLD` supplied as the reason (see Section 25.6.2.3, “Event Buffer Reporting in the Cluster Log”). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the `Ndb::setEventBufferQueueEmptyEpoch()` method from the NDB API.

### `ndb_report_thresh_binlog_mem_usage`

- **Command-Line Format**: `--ndb-report-thresh-binlog-mem-usage=#`
- **System Variable**: `ndb_report_thresh_binlog_mem_usage`
- **Scope**: Global
- **Dynamic**: Yes
- **SET_VAR Hint Applies**: No
- **Type**: Integer
- **Default Value**: 10
- **Minimum Value**: 0
- **Maximum Value**: 256

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

### `ndb_row_checksum`

- **System Variable**: `ndb_row_checksum`
- **Scope**: Global, Session
Traditionally, NDB has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting `ndb_row_checksum` to 0 means that row checksums are **not used** for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

- **ndb_schema_dist_lock_wait_timeout**

  Command-Line Format: `--ndb-schema-dist-lock-wait-timeout=value`

  System Variable: `ndb_schema_dist_lock_wait_timeout`

  Scope: Global

  Dynamic: Yes

  SET_VAR Hint Applies: No

  Type: Integer

  Default Value: 30

  Minimum Value: 0

  Maximum Value: 1200

  Unit: seconds

  Number of seconds to wait during schema distribution for the metadata lock taken on each SQL node in order to change its local data dictionary to reflect the DDL statement change. After this time has elapsed, a warning is returned to the effect that a given SQL node's data dictionary was not updated with the change. This avoids having the binary logging thread wait an excessive length of time while handling schema operations.

- **ndb_schema_dist_timeout**

  Command-Line Format: `--ndb-schema-dist-timeout=value`

  System Variable: `ndb_schema_dist_timeout`

  Scope: Global

  Dynamic: No

  SET_VAR Hint Applies: No

  Type: Integer

  Default Value: 120

  Minimum Value: 5

  Maximum Value: 1200

  Unit: seconds

  Number of seconds to wait before detecting a timeout during schema distribution. This can indicate that other SQL nodes are experiencing excessive activity, or that they are somehow being prevented from acquiring necessary resources at this time.

- **ndb_schema_dist_upgrade_allowed**
### ndb_schema_dist_upgrade_allowed

**Command-Line Format**

|--ndb-schema-dist-upgrade-allowed=value

**System Variable**

ndb_schema_dist_upgrade_allowed

**Scope**

Global

**Dynamic**

No

**SET_VAR Hint Applies**

No

**Type**

Boolean

**Default Value**

true

Allow upgrading of the schema distribution table when connecting to NDB. When true (the default), this change is deferred until all SQL nodes have been upgraded to the same version of the NDB Cluster software.

**Note**

The performance of the schema distribution may be somewhat degraded until the upgrade has been performed.

- **ndb_show_foreign_key_mock_tables**

**Command-Line Format**

|--ndb-show-foreign-key-mock-tables=[OFF|ON]

**System Variable**

ndb_show_foreign_key_mock_tables

**Scope**

Global

**Dynamic**

Yes

**SET_VAR Hint Applies**

No

**Type**

Boolean

**Default Value**

OFF

Show the mock tables used by NDB to support foreign_key_checks=0. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of SHOW CREATE TABLE.

- **ndb_slave_conflict_role**

**Command-Line Format**

|--ndb-slave-conflict-role=value

**Deprecated**

Yes

**System Variable**

ndb_slave_conflict_role

**Scope**

Global

**Dynamic**

Yes

**SET_VAR Hint Applies**

No

**Type**

Enumeration

**Default Value**

NONE

**Valid Values**

NONE

PRIMARY

SECONDARY
NDB Cluster Configuration Files

PASS

Deprecated synonym for ndb_conflict_role.

- **ndb_table_no_logging**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_table_no_logging</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

  When this variable is set to ON or 1, it causes all tables created or altered using ENGINE NDB to be nonlogging; that is, no data changes for this table are written to the redo log or checkpointed to disk, just as if the table had been created or altered using the NOLOGGING option for CREATE TABLE or ALTER TABLE.

  For more information about nonlogging NDB tables, see NDB_TABLE Options.

  ndb_table_no_logging has no effect on the creation of NDB table schema files; to suppress these, use ndb_table_temporary instead.

- **ndb_table_temporary**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_table_temporary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

  When set to ON or 1, this variable causes NDB tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

  **Note**
  Setting this variable currently has no effect. This is a known issue; see Bug #34036.

- **ndb_use_copyingAlterTable**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_use_copyingAlterTable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

  Forces NDB to use copying of tables in the event of problems with online ALTER TABLE operations. The default value is OFF.

- **ndb_use_exact_count**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_use_exact_count</th>
</tr>
</thead>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Forces NDB to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is OFF, which allows for faster queries overall.

- **ndb_use_transactions**

  Command-Line Format: `--ndb-use-transactions[={OFF|ON}]`
  System Variable: `ndb_use_transactions`
  Scope: Global, Session
  Dynamic: Yes
  SET_VAR Hint Applies: No
  Type: Boolean
  Default Value: ON

You can disable NDB transaction support by setting this variable's value to OFF. This is generally not recommended, although it may be useful to disable transaction support within a given client session when that session is used to import one or more dump files with large transactions; this allows a multi-row insert to be executed in parts, rather than as a single transaction. In such cases, once the import has been completed, you should either reset the variable value for this session to ON, or simply terminate the session.

- **ndb_version**

  System Variable: `ndb_version`
  Scope: Global
  Dynamic: No
  SET_VAR Hint Applies: No
  Type: String
  Default Value

  NDB engine version, as a composite integer.

- **ndb_version_string**

  System Variable: `ndb_version_string`
  Scope: Global
  Dynamic: No
  SET_VAR Hint Applies: No
  Type: String
  Default Value

  NDB engine version in `ndb-x.y.z` format.

- **replica_allow_batching**

  Command-Line Format: `--replica-allow-batching[={OFF|ON}]`
Whether or not batched updates are enabled on NDB Cluster replicas.

Allowing batched updates on the replica greatly improves performance, particularly when replicating TEXT, BLOB, and JSON columns. For this reason, `replica_allow_batching` is enabled by default.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 8.4, it is present but does nothing. For more information, see Section 25.7.6, “Starting NDB Cluster Replication (Single Replication Channel)”.

- **ndb_replica_batch_size**

  Determines the batch size in bytes used by the replication applier thread. Set this variable rather than the `--ndb-batch-size` option to apply this setting to the replica, exclusive of any other sessions.

  If this variable is unset (default 2 MB), its effective value is the greater of the value of `--ndb-batch-size` and 2 MB.

- **ndb_replica_blob_write_batch_bytes**
Control the batch write size used for blob data by the replication applier thread.

Use this variable rather than the `--ndb-blob-write-batch-bytes` option to control the blob batch write size on the replica, exclusive of any other sessions. The reason for this is that, when `ndb_replica_blob_write_batch_bytes` is not set, the effective blob batch size (that is, the maximum number of pending bytes to write for blob columns) is determined by the greater of the value of `--ndb-blob-write-batch-bytes` and 2 MB (the default for `ndb_replica_blob_write_batch_bytes`).

Setting `ndb_replica_blob_write_batch_bytes` to 0 means that NDB imposes no limit on the size of blob batch writes on the replica.

- **server_id_bits**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--server-id-bits=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>server_id_bits</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>7</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32</td>
</tr>
</tbody>
</table>

This variable indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (NDB Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `server_id_bits` variable is used to mask out any irrelevant bits of `server_id` in the I/O and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `server_id_bits` variable set to 32 (the default).

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 8.4 Server.

- **slave_allow_batching**

  | Command-Line Format | `--slave-allow-batching[={OFF|ON}]` |
  |---------------------|------------------------------------|
  | Deprecated          | Yes                                |
  | System Variable     | `slave_allow_batching`             |
  | Scope               | Global                             |
  | Dynamic             | Yes                                |
  | `SET_VAR` Hint Applies | No                    |
  | Type                | Boolean                            |
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Default Value</th>
<th>ON</th>
</tr>
</thead>
</table>

*Deprecated synonym for *`replica_allow_batching`*.  

**transaction_allow_batching**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>transaction_allow_batching</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When set to 1 or **ON**, this variable enables batching of statements within the same transaction. To use this variable, *autocommit* must first be disabled by setting it to 0 or **OFF**; otherwise, setting *transaction_allow_batching* has no effect.

It is safe to use this variable with transactions that perform writes only, as having it enabled can lead to reads from the "before" image. You should ensure that any pending transactions are committed (using an explicit *COMMIT* if desired) before issuing a *SELECT*.

**Important**

*transaction_allow_batching* should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the *ndbinfo* information database.

**ndbinfo_database**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndbinfo_database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndbinfo</td>
</tr>
</tbody>
</table>

Shows the name used for the *NDB* information database; the default is *ndbinfo*. This is a read-only variable whose value is determined at compile time.

**ndbinfo_max_bytes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndbinfo-max-bytes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndbinfo_max_bytes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4024</td>
</tr>
</tbody>
</table>
### ndbinfo_max_rows

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndbinfo-max-rows=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndbinfo_max_rows</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

### ndbinfo_offline

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>ndbinfo_offline</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Place the **ndbinfo** database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in NDB. No rows are returned from such tables (or views).

### ndbinfo_show_hidden

| Command-Line Format | `--ndbinfo-show-hidden=[{OFF|ON}]` |
|---------------------|-----------------------------------|
| System Variable     | `ndbinfo_show_hidden`             |
| Scope               | Global, Session                  |
| Dynamic             | Yes                              |
| `SET_VAR` Hint Applies | No                        |
| Type                | Boolean                          |
| Default Value       | OFF                              |
| Valid Values        | ON                               |
Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

**Note**
When `ndbinfo_show_hidden` is enabled, the internal tables are shown in the `ndbinfo` database only; they are not visible in `TABLES` or other `INFORMATION_SCHEMA` tables, regardless of the variable's setting.

- **ndbinfo_table_prefix**
  - **System Variable**: `ndbinfo_table_prefix`
  - **Scope**: Global
  - **Dynamic**: No
  - **SET_VAR Hint Applies**: No
  - **Type**: String
  - **Default Value**: `ndb$

  The prefix used in naming the `ndbinfo` database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`; the prefix itself is determined at compile time.

- **ndbinfo_version**
  - **System Variable**: `ndbinfo_version`
  - **Scope**: Global
  - **Dynamic**: No
  - **SET_VAR Hint Applies**: No
  - **Type**: String
  - **Default Value**:

  Shows the version of the `ndbinfo` engine in use; read-only.

### NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the NDB storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see Section 7.1.10, "Server Status Variables".

- **Handler_discover**

  The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- **Ndb_api_adaptive_send_deferred_count**

  Number of adaptive send calls that were not actually sent.

  For more information, see Section 25.6.16, "NDB API Statistics Counters and Variables".

- **Ndb_api_adaptive_send_deferred_count_session**

  Number of adaptive send calls that were not actually sent.
For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_deferred_count_replica**
  Number of adaptive send calls that were not actually sent by this replica.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_deferred_count_slave**
  Deprecated synonym for **Ndb_api_adaptive_send_deferred_count_replica**.

- **Ndb_api_adaptive_send_forced_count**
  Number of adaptive send calls using forced-send sent by this MySQL Server (SQL node).
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_forced_count_session**
  Number of adaptive send calls using forced-send sent in this client session.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_forced_count_replica**
  Number of adaptive send calls using forced-send sent by this replica.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_forced_count_slave**
  Deprecated synonym for **Ndb_api_adaptive_send_forced_count_replica**.

- **Ndb_api_adaptive_send_unforced_count**
  Number of adaptive send calls without forced-send sent by this MySQL server (SQL node).
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_unforced_count_session**
  Number of adaptive send calls without forced-send sent in this client session.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_unforced_count_replica**
  Number of adaptive send calls without forced-send sent by this replica.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_unforced_count_slave**
  Deprecated synonym for **Ndb_api_adaptive_send_unforced_count_replica**.

- **Ndb_api_bytes_sent_count_session**
  Amount of data (in bytes) sent to the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.
• **Ndb_api_bytes_sent_count_replica**
  
  Amount of data (in bytes) sent to the data nodes by this replica.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.
  
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_sent_count_slave**
  
  Deprecated synonym for **Ndb_api_bytes_sent_count_replica**.

• **Ndb_api_bytes_sent_count**
  
  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_received_count_session**
  
  Amount of data (in bytes) received from the data nodes in this client session.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this *mysqld*.
  
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_received_count_replica**
  
  Amount of data (in bytes) received from the data nodes by this replica.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.
  
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_received_count_slave**
  
  Deprecated synonym for **Ndb_api_bytes_received_count_replica**.

• **Ndb_api_bytes_received_count**
  
  Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_event_data_count_injector**
  
  The number of row change events received by the NDB binlog injector thread.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

NDB Cluster Configuration Files

- **Ndb_api_event_data_count**
  
The number of row change events received by this MySQL Server (SQL node).
  
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count_injector**
  
The number of events received, other than row change events, by the NDB binary log injector thread.
  
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count**
  
The number of events received, other than row change events, by this MySQL Server (SQL node).
  
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count_injector**
  
The number of bytes of events received by the NDB binlog injector thread.
  
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count**
  
The number of bytes of events received by this MySQL Server (SQL node).
  
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_session**
  
The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.
  
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
  
For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

4029
• **Ndb_api_pk_op_count_replica**

The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_pk_op_count_slave**

Deprecated synonym for **Ndb_api_pk_op_count_replica**.

• **Ndb_api_pk_op_count**

The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_pruned_scan_count_session**

The number of scans in this client session that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_pruned_scan_count_replica**

The number of scans by this replica that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_pruned_scan_count_slave**

Deprecated synonym for **Ndb_api_pruned_scan_count_replica**.

• **Ndb_api_pruned_scan_count**

The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.
• **Ndb_api_range_scan_count_session**

The number of range scans that have been started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 25.6.16, "NDB API Statistics Counters and Variables".

• **Ndb_api_range_scan_count_replica**

The number of range scans that have been started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.16, "NDB API Statistics Counters and Variables".

• **Ndb_api_range_scan_count_slave**

Deprecated synonym for **Ndb_api_range_scan_count_replica**.

• **Ndb_api_range_scan_count**

The number of range scans that have been started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.16, "NDB API Statistics Counters and Variables".

• **Ndb_api_read_row_count_session**

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 25.6.16, "NDB API Statistics Counters and Variables".

• **Ndb_api_read_row_count_replica**

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.16, "NDB API Statistics Counters and Variables".

• **Ndb_api_read_row_count_slave**

Deprecated synonym for **Ndb_api_read_row_count_replica**.
• **Ndb_api_read_row_count**

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  You should be aware that this value may not be completely accurate with regard to rows read by `SELECT COUNT(*)` queries, due to the fact that, in this case, the MySQL server actually reads pseudo-rows in the form `[table fragment ID]:[number of rows in fragment]` and sums the rows per fragment for all fragments in the table to derive an estimated count for all rows. **Ndb_api_read_row_count** uses this estimate and not the actual number of rows in the table.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_scan_batch_count_session**

  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_scan_batch_count_replica**

  The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_scan_batch_count_slave**

  Deprecated synonym for **Ndb_api_scan_batch_count_replica**.

• **Ndb_api_scan_batch_count**

  The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_table_scan_count_session**

  The number of table scans that have been started in this client session, including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.
• **Ndb_api_table_scan_count_replica**

The number of table scans that have been started by this replica, including scans of internal tables.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_table_scan_count_slave**

Deprecated synonym for `Ndb_api_table_scan_count_replica`.

• **Ndb_api_table_scan_count**

The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count_session**

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count_replica**

The number of transactions aborted by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count_slave**

Deprecated synonym for `Ndb_api_trans_abort_count_replica`.

• **Ndb_api_trans_abort_count**

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.
NDB Cluster Configuration Files

• **Ndb_api_trans_close_count_session**

  The number of transactions closed in this client session. This value may be greater than the sum of **Ndb_api_trans_commit_count_session** and **Ndb_api_trans_abort_count_session**, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_close_count_replica**

  The number of transactions closed by this replica. This value may be greater than the sum of **Ndb_api_trans_commit_count_replica** and **Ndb_api_trans_abort_count_replica**, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_close_count_slave**

  Deprecated synonym for **Ndb_api_trans_close_count_replica**.

• **Ndb_api_trans_close_count**

  The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of **Ndb_api_trans_commit_count** and **Ndb_api_trans_abort_count**, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_commit_count_session**

  The number of transactions committed in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_commit_count_replica**

  The number of transactions committed by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_commit_count_slave**

  Deprecated synonym for **Ndb_api_trans_commit_count_replica**.
NDB Cluster Configuration Files

- **Ndb_api_trans_commit_count**
  The number of transactions committed by this MySQL Server (SQL node).
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_local_read_row_count_session**
  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_local_read_row_count_replica**
  The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_local_read_row_count_slave**
  Deprecated synonym for `Ndb_api_trans_local_read_row_count_replica`.

- **Ndb_api_trans_local_read_row_count**
  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_start_count_session**
  The number of transactions started in this client session.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_start_count_replica**
  The number of transactions started by this replica.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.
  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”. 

4035
NDB Cluster Configuration Files

- **Ndb_api_trans_start_count_slave**
  
  Deprecated synonym for `Ndb_api_trans_start_count_replica`.

- **Ndb_api_trans_start_count**
  
  The number of transactions started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_uk_op_count_session**
  
  The number of operations in this client session based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_uk_op_count_replica**
  
  The number of operations by this replica based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_uk_op_count_slave**
  
  Deprecated synonym for `Ndb_api_uk_op_count_replica`.

- **Ndb_api_uk_op_count**
  
  The number of operations by this MySQL Server (SQL node) based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count_session**
  
  The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

4036
• **Ndb_api_wait_exec_complete_count_replica**

  The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_exec_complete_count_slave**

  Deprecated synonym for `Ndb_api_wait_exec_complete_count_replica`.

• **Ndb_api_wait_exec_complete_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_meta_request_count_session**

  The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_meta_request_count_replica**

  The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_meta_request_count_slave**

  Deprecated synonym for `Ndb_api_wait_meta_request_count_replica`.

• **Ndb_api_wait_meta_request_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

  4037
• **Ndb_api_wait_nanos_count_session**

  Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this mysqld.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count_replica**

  Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count_slave**

  Deprecated synonym for `Ndb_api_wait_nanos_count_replica`.

• **Ndb_api_wait_nanos_count**

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count_session**

  The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this mysqld.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count_replica**

  The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count_slave**

  Deprecated synonym for `Ndb_api_wait_scan_result_count_replica`.
NDB Cluster Configuration Files

- **Ndb_api_wait_scan_result_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.16, “NDB API Statistics Counters and Variables”.

- **Ndb_cluster_node_id**

  If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_config_from_host**

  If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- **Ndb_config_from_port**

  If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_config_generation**

  Shows the generation number of the cluster's current configuration. This can be used as an indicator to determine whether the configuration of the cluster has changed since this SQL node last connected to the cluster.

- **Ndb_conflict_fn_epoch**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch_trans**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch2**

  Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()` on the source designated as the primary since the last time it was restarted.

  For more information, see `NDB$EPOCH2()`.
• **Ndb_conflict_fn_epoch2_trans**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to
  be in conflict using \texttt{NDB\$EPOCH\_TRANS2()} conflict resolution on a given \texttt{mysqld} since the last time
  it was restarted.

  For more information, see \texttt{NDB\$EPOCH2\_TRANS()}.

• **Ndb_conflict_fn_max**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a
  row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution
  since the last time that this \texttt{mysqld} was started.

  For more information, see \texttt{Section 25.7.12, “NDB Cluster Replication Conflict Resolution”}.

• **Ndb_conflict_fn_max_del_win**

  Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster
  Replication conflict resolution using \texttt{NDB\$MAX\_DELETE\_WIN()}, since the last time that this \texttt{mysqld}
  was started.

  For more information, see \texttt{Section 25.7.12, “NDB Cluster Replication Conflict Resolution”}.

• **Ndb_conflict_fn_max_del_win_ins**

  Shows the number of times that insertion of a row was rejected on the current SQL node due to NDB
  Cluster Replication conflict resolution using \texttt{NDB\$MAX\_DEL\_WIN\_INS()}, since the last time that this \texttt{mysqld}
  was started.

  For more information, see \texttt{Section 25.7.12, “NDB Cluster Replication Conflict Resolution”}.

• **Ndb_conflict_fn_max_ins**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a
  row was not inserted on the current SQL node due to “greatest timestamp wins” conflict resolution
  since the last time that this \texttt{mysqld} was started.

  For more information, see \texttt{Section 25.7.12, “NDB Cluster Replication Conflict Resolution”}.

• **Ndb_conflict_fn_old**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a
  row was not applied as the result of “same timestamp wins” conflict resolution on a given \texttt{mysqld}
  since the last time it was restarted.

  For more information, see \texttt{Section 25.7.12, “NDB Cluster Replication Conflict Resolution”}.

• **Ndb_conflict_last_conflict_epoch**

  The most recent epoch in which a conflict was detected on this replica. You can compare this value
  with \texttt{Ndb_replica_max_replicated_epoch}; if \texttt{Ndb_replica_max_replicated_epoch} is
  greater than \texttt{Ndb_conflict_last_conflict_epoch}, no conflicts have yet been detected.

  See \texttt{Section 25.7.12, “NDB Cluster Replication Conflict Resolution”}, for more information.

• **Ndb_conflict_reflected_op_discard_count**

  When using NDB Cluster Replication conflict resolution, this is the number of reflected operations
  that were not applied on the secondary, due to encountering an error during execution.

  See \texttt{Section 25.7.12, “NDB Cluster Replication Conflict Resolution”}, for more information.
NDB Cluster Configuration Files

• **Ndb_conflict_reflected_op_prepare_count**

When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

See Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_refresh_op_count**

When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

See Section 25.7.12, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_last_stable_epoch**

Number of rows found to be in conflict by a transactional conflict function

See Section 25.7.12, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_trans_row_conflict_count**

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given mysqld since the last time it was restarted.

Currently, the only transactional conflict detection function supported by NDB Cluster is NDB$EPOCH_TRANS(), so this status variable is effectively the same as Ndb_conflict_fn_epoch_trans.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_row_reject_count**

Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only Ndb_conflict_trans_row_conflict_count, but any rows in or dependent on conflicting transactions.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_reject_count**

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_detect_iter_count**

Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_conflict_commit_count**

Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

4041
• **Ndb\_epoch\_delete\_delete\_count**

  When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

• **Ndb\_execute\_count**

  Provides the number of round trips to the NDB kernel made by operations.

• **Ndb\_last\_commit\_epoch\_server**

  The epoch most recently committed by NDB.

• **Ndb\_last\_commit\_epoch\_session**

  The epoch most recently committed by this NDB client.

• **Ndb\_metadata\_detected\_count**

  The number of times since this server was last started that the NDB metadata change detection thread has discovered changes with respect to the MySQL data dictionary.

• **Ndb\_metadata\_excluded\_count**

  The number of metadata objects that the NDB binlog thread has been unable to synchronize on this SQL node since it was last restarted.

  Should an object be excluded, it is not again considered for automatic synchronization until the user corrects the mismatch manually. This can be done by attempting to use the table with a statement such as `SHOW CREATE TABLE table, SELECT * FROM table`, or any other statement that would trigger table discovery.

• **Ndb\_metadata\_synced\_count**

  The number of NDB metadata objects which have been synchronized on this SQL node since it was last restarted.

• **Ndb\_number\_of\_data\_nodes**

  If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

• **Ndb\_pushed\_queries\_defined**

  The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

  **Note**

  Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

• **Ndb\_pushed\_queries\_dropped**

  The number of joins that were pushed down to the NDB kernel but that could not be handled there.

• **Ndb\_pushed\_queries\_executed**

  The number of joins successfully pushed down to NDB and executed there.

• **Ndb\_pushed\_reads**

  The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down.
### Note

Executing `EXPLAIN` on joins that can be pushed down to NDB does not add to this number.

- **Ndb_pruned_scan_count**

  This variable holds a count of the number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

  Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving replica only a single data node.

- **Ndb_replica_max_replicated_epoch**

  The most recently committed epoch on this replica. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_replica_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_scan_count**

  This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started.

- **Ndb_slave_max_replicated_epoch**

  Deprecated synonym for `Ndb_replica_max_replicated_epoch`.

- **Ndb_system_name**

  If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

- **Ndb_trans_hint_count_session**

  The number of transactions using hints that have been started in the current session. Compare with `Ndb_api_trans_start_count_session` to obtain the proportion of all NDB transactions able to use hints.

### 25.4.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

**Note**

For an exception to this rule, see Section 25.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.
NDB Cluster Configuration Files

Important
Any [tcp] sections in the config.ini file should be listed last, following all other sections in the file. However, this is not required for a [tcp default] section. This requirement is a known issue with the way in which the config.ini file is read by the NDB Cluster management server.

Connection parameters which can be set in [tcp] and [tcp default] sections of the config.ini file are listed here:

- **AllowUnresolvedHostNames**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

By default, when a management node fails to resolve a host name while trying to connect, this results in a fatal error. This behavior can be overridden by setting AllowUnresolvedHostNames to true in the [tcp default] section of the global configuration file (usually named config.ini), in which case failure to resolve a host name is treated as a warning and ndb_mgmd startup continues uninterrupted.

- **Checksum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter is disabled by default. When it is enabled (set to Y or 1), checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- **Group**

  When ndb_optimized_node_selection is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

- **HostName1**
The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **NodeId1**

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of **NodeId1** and **NodeId2**. These are the same unique **Id** values for each of these nodes as described in Section 25.4.3.7, "Defining SQL and Other API Nodes in an NDB Cluster".
NDB Cluster Configuration Files

- **NodeId2**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **NodeIdServer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 63</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Set the server side of a TCP connection.

- **OverloadLimit**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”, for more information.
NDB Cluster Configuration Files

- **PreferIPVersion**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>4</td>
</tr>
<tr>
<td>Range</td>
<td>4, 6</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial System Restart:</strong> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

 Determines the preference of DNS resolution for IP version 4 or version 6. Because the configuration retrieval mechanism employed by NDB Cluster requires that all connections use the same preference, this parameter should be set in the [tcp default] of the config.ini global configuration file.

- **PreSendChecksum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

 If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if Checksum is not also enabled.

- **Proxy**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>
Set a proxy for the TCP connection.

- **ReceiveBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>16K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- **RequireLinkTls**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

If the node at either endpoint of this TCP connection requires TLS authentication, the value of this parameter is **true**, otherwise **false**. The value is set by **NDB**, and cannot be changed by the user.

- **SendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart</td>
</tr>
</tbody>
</table>

4048
TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, \texttt{TotalSendBufferMemory}) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false (debug builds: true)</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to \texttt{Y}, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in \texttt{-debug} builds.

- **TcpBind_INADDR_ANY**

Setting this parameter to \texttt{TRUE} or \texttt{1} binds \texttt{IP_ADDR_ANY} so that connections can be made from anywhere (for autogenerated connections). The default is \texttt{FALSE (0)}.

- **TcpSpinTime**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>µsec</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Controls spin for a TCP transporter; no enable, set to a nonzero value. This works for both the data node and management or SQL node side of the connection.
NDB Cluster Configuration Files

- **TCP_MAXSEG_SIZE**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
</tbody>
</table>

**Restart Type**

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.4.0)

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- **TCP_RCV_BUF_SIZE**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>

25.4.3.11 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the \texttt{[tcp]} section of the cluster \texttt{config.ini} file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the 172.23.72.* subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.* address range as shown:

```plaintext
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22
[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The \texttt{HostName1} and \texttt{HostName2} parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

\textbf{Note}

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.
25.4.3.12 NDB Cluster Shared-Memory Connections

Communications between NDB cluster nodes are normally handled using TCP/IP. The shared memory (SHM) transporter is distinguished by the fact that signals are transmitted by writing in memory rather than on a socket. The shared-memory transporter (SHM) can improve performance by negating up to 20% of the overhead required by a TCP connection when running an API node (usually an SQL node) and a data node together on the same host. You can enable a shared memory connection in either of the two ways listed here:

- By setting the `UseShm` data node configuration parameter to 1, and setting `HostName` for the data node and `HostName` for the API node to the same value.
- By using `[shm]` sections in the cluster configuration file, each containing settings for `NodeId1` and `NodeId2`. This method is described in more detail later in this section.

Suppose a cluster is running a data node which has node ID 1 and an SQL node having node ID 51 on the same host computer at 10.0.0.1. To enable an SHM connection between these two nodes, all that is necessary is to insure that the following entries are included in the cluster configuration file:

```
[ndbd]
NodeId=1
HostName=10.0.0.1
UseShm=1

[mysqld]
NodeId=51
HostName=10.0.0.1
```

**Important**
The two entries just shown are in addition to any other entries and parameter settings needed by the cluster. A more complete example is shown later in this section.

Before starting data nodes that use SHM connections, it is also necessary to make sure that the operating system on each computer hosting such a data node has sufficient memory allocated to shared memory segments. See the documentation for your operating platform for information regarding this. In setups where multiple hosts are each running a data node and an API node, it is possible to enable shared memory on all such hosts by setting `UseShm` in the `[ndbd default]` section of the configuration file. This is shown in the example later in this section.

While not strictly required, tuning for all SHM connections in the cluster can be done by setting one or more of the following parameters in the `[shm default]` section of the cluster configuration (config.ini) file:

- `ShmSize`: Shared memory size
- `ShmSpinTime`: Time in µs to spin before sleeping
- `SendBufferMemory`: Size of buffer for signals sent from this node, in bytes.
- `SendSignalId`: Indicates that a signal ID is included in each signal sent through the transporter.
- `Checksum`: Indicates that a checksum is included in each signal sent through the transporter.
- `PreSendChecksum`: Checks of the checksum are made prior to sending the signal; Checksum must also be enabled for this to work

This example shows a simple setup with SHM connections defined on multiple hosts, in an NDB Cluster using 3 computers listed here by host name, hosting the node types shown:

1. 10.0.0.0: The management server
2. 10.0.0.1: A data node and an SQL node
### 3. 10.0.0.2: A data node and an SQL node

In this scenario, each data node communicates with both the management server and the other data node using TCP transporters; each SQL node uses a shared memory transporter to communicate with the data nodes that is local to it, and a TCP transporter to communicate with the remote data node. A basic configuration reflecting this setup is enabled by the config.ini file whose contents are shown here:

```
[ndbd default]
DataDir=/path/to/datadir
UseShm=1

[shm default]
ShmSize=8M
ShmSpintime=200
SendBufferMemory=4M

[tcp default]
SendBufferMemory=8M

[ndb_mgmd]
NodeId=49
Hostname=10.0.0.0
DataDir=/path/to/datadir

[ndbd]
NodeId=1
Hostname=10.0.0.1
DataDir=/path/to/datadir

[ndbd]
NodeId=2
Hostname=10.0.0.2
DataDir=/path/to/datadir

[mysqld]
NodeId=51
Hostname=10.0.0.1

[mysqld]
NodeId=52
Hostname=10.0.0.2

[api]
[api]
```

Parameters affecting all shared memory transporters are set in the [shm default] section; these can be overridden on a per-connection basis in one or more [shm] sections. Each such section must be associated with a given SHM connection using NodeId1 and NodeId2; the values required for these parameters are the node IDs of the two nodes connected by the transporter. You can also identify the nodes by host name using HostName1 and HostName2, but these parameters are not required.

The API nodes for which no host names are set use the TCP transporter to communicate with data nodes independent of the hosts on which they are started; the parameters and values set in the [tcp default] section of the configuration file apply to all TCP transporters in the cluster.

For optimum performance, you can define a spin time for the SHM transporter (ShmSpinTime parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in NDB.

- **Checksum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Range</th>
<th>true, false</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Restart Type</strong></td>
<td><a href="#">Node Restart:</a> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter is a boolean (\text{Y}/\text{N}) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- **Group**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>35</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 200</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><a href="#">Node Restart:</a> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- **HostName1**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><a href="#">Node Restart:</a> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
</tbody>
</table>
The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **NodeId1**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **NodeId2**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **NodeIdServer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 63</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart</td>
</tr>
</tbody>
</table>
Identify the server end of a shared memory connection. By default, this is the node ID of the data node.

- **OverloadLimit**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 25.4.3.14, "Configuring NDB Cluster Send Buffer Parameters", and Section 25.6.17.66, "The ndbinfo transporters Table", for more information.

- **PreSendChecksum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

If this parameter and **Checksum** are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if **Checksum** is not also enabled.

- **SendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>
Size (in bytes) of the shared memory buffer for signals sent from this node using a shared memory connection.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **ShmKey**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value. If `UseShm` is enabled, the shared memory key is calculated automatically by `NDB`.

- **ShmSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>4M</td>
</tr>
<tr>
<td>Range</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart</td>
</tr>
</tbody>
</table>
Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 4MB.

- **ShmSpinTime**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

When receiving, the time to wait before sleeping, in microseconds.

- **SigNum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.6)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.4.0)</td>
</tr>
</tbody>
</table>

This parameter was formerly used to override operating system signal numbers; in NDB 8.4, it is no longer used, and any setting for it is ignored.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.21 NDB Cluster restart types**

<table>
<thead>
<tr>

<td>All cluster nodes must be shut down completely, then...</td>
</tr>
</tbody>
</table>
### 25.4.3.13 Data Node Memory Management

All memory allocation for a data node is performed when the node is started. This ensures that the data node can run in a stable manner without using swap memory, so that NDB can be used for latency-sensitive (realtime) applications. The following types of memory are allocated on data node startup:

- Data memory
- Shared global memory
- Redo log buffers
- Job buffers
- Send buffers
- Page cache for disk data records
- Schema transaction memory
- Transaction memory
- Undo log buffer
- Query memory
- Block objects
- Schema memory
- Block data structures
- Long signal memory
- Shared memory communication buffers

The NDB memory manager, which regulates most data node memory, handles the following memory resources:

- Data Memory (`DataMemory`)
- Redo log buffers (`RedoBuffer`)
- Job buffers
- Send buffers (`SendBufferMemory, TotalSendBufferMemory, ExtraSendBufferMemory`)
- Disk Data record page cache (`DiskPageBufferMemory, DiskPageBufferEntries`)
- Transaction memory (`TransactionMemory`)
- Query memory
- Disk access records
- File buffers

Each of these resources is set up with a reserved memory area and a maximum memory area. The reserved memory area can be used only by the resource for which it is reserved and cannot be shared.
with other resources; a given resource can never allocate more than the maximum memory allowed for the resource. A resource that has no maximum memory can expand to use all the shared memory in the memory manager.

The size of the global shared memory for these resources is controlled by the `SharedGlobalMemory` configuration parameter (default: 128 MB).

Data memory is always reserved and never acquires any memory from shared memory. It is controlled using the `DataMemory` configuration parameter, whose maximum is 16384 GB. `DataMemory` is where records are stored, including hash indexes (approximately 15 bytes per row), ordered indexes (10-12 bytes per row per index), and row headers (16-32 bytes per row).

Redo log buffers also use reserved memory only; this is controlled by the `RedoBuffer` configuration parameter, which sets the size of the redo log buffer per LDM thread. This means that the actual amount of memory used is the value of this parameter multiplied by the number of LDM threads in the data node.

Job buffers use reserved memory only; the size of this memory is calculated by `NDB`, based on the numbers of threads of various types.

Send buffers have a reserved part but can also allocate an additional 25% of shared global memory. The send buffer reserved size is calculated in two steps:

1. Use the value of the `TotalSendBufferMemory` configuration parameter (no default value) or the sum of the individual send buffers used by all individual connections to the data node. A data node is connected to all other data nodes, to all API nodes, and to all management nodes. This means that, in a cluster with 2 data nodes, 2 management nodes, and 10 API nodes each data node has 13 node connections. Since the default value for `SendBufferMemory` for a data node connection is 2 MByte, this works out to 26 MB total.

2. To obtain the total reserved size for the send buffer, the value of the `ExtraSendBufferMemory` configuration parameter, if any (default value 0), is added to the value obtained in the previous step. In other words, if `TotalSendBufferMemory` has been set, the send buffer size is `TotalSendBufferMemory + ExtraSendBufferMemory`; otherwise, the size of the send buffer is equal to `(number of node connections) * SendBufferMemory) + ExtraSendBufferMemory`.

The page cache for disk data records uses a reserved resource only; the size of this resource is controlled by the `DiskPageBufferMemory` configuration parameter (default 64 MB). Memory for 32 KB disk page entries is also allocated; the number of these is determined by the `DiskPageBufferEntries` configuration parameter (default 10).

Transaction memory has a reserved part that either is calculated by `NDB`, or is set explicitly using the `TransactionMemory` configuration parameter; transaction memory can also use an unlimited amount of shared global memory. Transaction memory is used for all operational resources handling transactions, scans, locks, scan buffers, and trigger operations. It also holds table rows as they are updated, before the next commit writes them to data memory.

Resources are allocated from a common transaction memory resource and can also use resources from global shared memory. the size of this resource can be controlled using a single `TransactionMemory` configuration parameter.

Reserved memory for undo log buffers can be set using the `InitialLogFileGroup` configuration parameter. If an undo log buffer is created as part of a `CREATE LOGFILE GROUP` SQL statement, the memory is taken from the transaction memory.

A number of resources relating to metadata for Disk Data resources also have no reserved part, and use shared global memory only. Shared global shared memory is thus shared between send buffers, transaction memory, and Disk Data metadata.

If `TransactionMemory` is not set, it is calculated based on the following parameters:
NDB Cluster Configuration Files

- MaxNoOfConcurrentOperations
- MaxNoOfConcurrentTransactions
- MaxNoOfFiredTriggers
- MaxNoOfLocalOperations
- MaxNoOfConcurrentIndexOperations
- MaxNoOfConcurrentScans
- MaxNoOfLocalScans
- BatchSizePerLocalScan
- TransactionBufferMemory

When `TransactionMemory` is set explicitly, none of the configuration parameters just listed are used to calculate memory size. In addition, the parameters `MaxNoOfConcurrentIndexOperations`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` are incompatible with `TransactionMemory` and cannot be set concurrently with it; if `TransactionMemory` is set and any of these four parameters are also set in the `config.ini` configuration file, the management server cannot start.

The `MaxNoOfConcurrentIndexOperations`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` parameters are all deprecated; you should expect them to be removed from a future release of MySQL NDB Cluster.

The transaction memory resource contains a large number of memory pools. Each memory pool represents an object type and contains a set of objects; each pool includes a reserved part allocated to the pool at startup; this reserved memory is never returned to shared global memory. Reserved records are found using a data structure having only a single level for fast retrieval, which means that a number of records in each pool should be reserved. The number of reserved records in each pool has some impact on performance and reserved memory allocation, but is generally necessary only in certain very advanced use cases to set the reserved sizes explicitly.

The size of the reserved part of the pool can be controlled by setting the following configuration parameters:

- `ReservedConcurrentIndexOperations`
- `ReservedFiredTriggers`
- `ReservedConcurrentOperations`
- `ReservedLocalScans`
- `ReservedConcurrentTransactions`
- `ReservedConcurrentScans`
- `ReservedTransactionBufferMemory`

For any of the parameters just listed that is not set explicitly in `config.ini`, the reserved setting is calculated as 25% of the corresponding maximum setting. For example, if unset, `ReservedConcurrentIndexOperations` is calculated as 25% of `MaxNoOfConcurrentIndexOperations`, and `ReservedLocalScans` is calculated as 25% of `MaxNoOfLocalScans`.

**Note**

If `ReservedTransactionBufferMemory` is not set, it is calculated as 25% of `TransactionBufferMemory`. 
The number of reserved records is per data node; these records are split among the threads handling them (LDM and TC threads) on each node. In most cases, it is sufficient to set `TransactionMemory` alone, and to allow the number of records in pools to be governed by its value.

`MaxNoOfConcurrentScans` limits the number of concurrent scans that can be active in each TC thread. This is important in guarding against cluster overload.

`MaxNoOfConcurrentOperations` limits the number of operations that can be active at any one time in updating transactions. (Simple reads are not affected by this parameter.) This number needs to be limited because it is necessary to preallocate memory for node failure handling, and a resource must be available for handling the maximum number of active operations in one TC thread when contending with node failures. It is imperative that `MaxNoOfConcurrentOperations` be set to the same number on all nodes (this can be done most easily by setting a value for it once, in the `[ndbd default]` section of the `config.ini` global configuration file). While its value can be increased using a rolling restart (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”), decreasing it in this way is not considered safe due to the possibility of a node failure occurring during the rolling restart.

It is possible to limit the size of a single transaction in NDB Cluster through the `MaxDMLOperationsPerTransaction` parameter. If this is not set, the size of one transaction is limited by `MaxNoOfConcurrentOperations` since this parameter limits the total number of concurrent operations per TC thread.

Schema memory size is controlled by the following set of configuration parameters:

- `MaxNoOfSubscriptions`
- `MaxNoOfSubscribers`
- `MaxNoOfConcurrentSubOperations`
- `MaxNoOfAttributes`
- `MaxNoOfTables`
- `MaxNoOfOrderedIndexes`
- `MaxNoOfUniqueHashIndexes`
- `MaxNoOfTriggers`

The number of nodes and the number of LDM threads also have a major impact on the size of schema memory since the number of partitions in each table and each partition (and its fragment replicas) have to be represented in schema memory.

In addition, a number of other records are allocated during startup. These are relatively small. Each block in each thread contains block objects that use memory. This memory size is also normally quite small compared to the other data node memory structures.

### 25.4.3.14 Configuring NDB Cluster Send Buffer Parameters

The NDB kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:
Using High-Speed Interconnects with NDB Cluster

<table>
<thead>
<tr>
<th>Transporter</th>
<th>Maximum Send Buffer Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>SendBufferMemory (default = 2M)</td>
</tr>
<tr>
<td>SHM</td>
<td>20K</td>
</tr>
</tbody>
</table>

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`Send Buffers overloaded in NDB kernel`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

### 25.4.4 Using High-Speed Interconnects with NDB Cluster

Even before design of NDBCLUSTER began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, NDBCLUSTER was designed from the very beginning to permit the use of a number of different data transport mechanisms, or transporters.

NDB Cluster supports three of these (see Section 25.2.1, “NDB Cluster Core Concepts”). A fourth transporter, Scalable Coherent Interface (SCI), was also supported in very old versions of NDB. This required specialized hardware, software, and MySQL binaries that are no longer available.

### 25.5 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (`ndbd`, `ndbmtd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

For information about using `mysqld` as an NDB Cluster process, see Section 25.6.10, “MySQL Server Usage for NDB Cluster”.

Other NDB utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

### 25.5.1 ndbd — The NDB Cluster Data Node Daemon
The `ndbd` binary provides the single-threaded version of the process that is used to handle all the data in tables employing the NDB CLUSTER storage engine. This data node process enables a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks. In NDB 8.4.1 and later, when started, `ndbd` logs a warning similar to that shown here:

```
2024-05-28 13:32:16 [ndbd] WARNING -- Running ndbd with a single thread of
signal execution. For multi-threaded signal execution run the ndbmtd binary.
```

`ndbmtd` is the multi-threaded version of this binary.

In an NDB Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

Options that can be used with `ndbd` are shown in the following table. Additional descriptions follow the table.

---

**Note**

All of these options also apply to the multithreaded version of this program (`ndbmtd`) and you may substitute "ndbmtd" for "ndbd" wherever the latter occurs in this section.

---

* **--bind-address**

  - **Command-Line Format**
    - `--bind-address=name`

  - **Type**
    - String

  - **Default Value**
    - Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

* **--character-sets-dir**

  - **Command-Line Format**
    - `--character-sets-dir=path`

  - Directory containing character sets.

* **--connect-delay=#**

  - **Command-Line Format**
    - `--connect-delay=#`

  - **Deprecated**
    - Yes

  - **Type**
    - Numeric

  - **Default Value**
    - 5

  - **Minimum Value**
    - 0

  - **Maximum Value**
    - 3600

  - Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

  - This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use `--connect-retry-delay` instead.

* **--connect-retries=#**

  - **Command-Line Format**
    - `--connect-retries=#`

  - **Type**
    - Numeric

  - **Default Value**
    - 4064

  - **Minimum Value**
    - 0

  - **Maximum Value**
    - 3600

  - Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the `--connect-retries` option).

---

4064
### ndbd — The NDB Cluster Data Node Daemon

<table>
<thead>
<tr>
<th>Type</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-retry-delay` option.

It is also possible to set this option to -1, in which case, the data node process continues indefinitely to try to connect.

- **`--connect-retry-delay=##`**

  **Command-Line Format**

  ```
  --connect-retry-delay=##
  ```

  **Type** Numeric
  **Default Value** 5
  **Minimum Value** 0
  **Maximum Value** 4294967295

  Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

  This option takes the place of the `--connect-delay` option, which is now deprecated and subject to removal in a future release of NDB Cluster.

  The short form `-r` for this option is also deprecated, and thus subject to removal. Use the long form instead.

- **`--connect-string`**

  **Command-Line Format**

  ```
  --connect-string=connection_string
  ```

  **Type** String
  **Default Value** [none]

  Same as `--ndb-connectstring`.

- **`--core-file`**

  **Command-Line Format**

  ```
  --core-file
  ```

  Write core file on error; used in debugging.

- **`--daemon, -d`**

  **Command-Line Format**

  ```
  --daemon
  ```

  Instructs `ndbd` or `ndbmtd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

  This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

- **`--defaults-extra-file`**

  **Command-Line Format**

  ```
  --defaults-extra-file=path
  ```

  **Type** String
ndbd — The NDB Cluster Data Node Daemon

<table>
<thead>
<tr>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

- **--defaults-file**

  **Command-Line Format**
  --defaults-file=path

  **Type**
  String

  **Default Value**
  [none]

Read default options from given file only.

- **--defaults-group-suffix**

  **Command-Line Format**
  --defaults-group-suffix=string

  **Type**
  String

  **Default Value**
  [none]

Also read groups with concat(group, suffix).

- **--filesystem-password**

  **Command-Line Format**
  --filesystem-password=password

  Pass the filesystem encryption and decryption password to the data node process using stdin, tty, or the my.cnf file.

  Requires EncryptedFileSystem = 1.

  For more information, see Section 25.6.14, “File System Encryption for NDB Cluster”.

- **--filesystem-password-from-stdin**

  **Command-Line Format**
  --filesystem-password-from-stdin={TRUE|FALSE}

  Pass the filesystem encryption and decryption password to the data node process from stdin (only).

  Requires EncryptedFileSystem = 1.

  For more information, see Section 25.6.14, “File System Encryption for NDB Cluster”.

- **--foreground**

  **Command-Line Format**
  --foreground

  Causes ndbd or ndbmtd to execute as a foreground process, primarily for debugging purposes. This option implies the --nodaemon option.

  This option has no effect when running ndbd or ndbmtd on Windows platforms.

- **--help**

  **Command-Line Format**
  --help

  Display help text and exit.

- **--initial**
Command-Line Format

--initial

Instructs ndbd to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of ndbd. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

The option also causes the removal of all data files associated with Disk Data tablespaces and undo log files associated with log file groups that existed previously on this data node (see Section 25.6.11, “NDB Cluster Disk Data Tables”).

An --initial start is to be used only when starting the ndbd process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of ndbd.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

**Warning**

To avoid the possibility of eventual data loss, it is recommended that you not use the --initial option together with StopOnError = 0. Instead, set StopOnError to 0 in config.ini only after the cluster has been started, then restart the data nodes normally—that is, without the --initial option. See the description of the StopOnError parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the StartPartialTimeout and StartPartitionedTimeout configuration parameters from having any effect.

**Important**

This option does not affect backup files that have already been created by the affected node.

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running (unless they also were started with --initial, as part of an initial restart). This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is not necessary to do so.

- --initial-start

Command-Line Format

--initial-start

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as --nowait-nodes.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
$> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
$> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
```
When using this option, you must also specify the node ID for the data node being started with the 
--ndb-nodeid option.

Important

Do not confuse this option with the --nowait-nodes option for ndb_mgmd, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

• --install[=name]

Command-Line Format: --install[=name]

Platform Specific: Windows

Type: String

Default Value: ndbd

Causes ndbd to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to ndbd. Although it is preferable to specify other ndbd program options in a my.ini or my.cnf configuration file, it is possible to use together with --install. However, in such cases, the --install option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the --initial option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other ndbd options that affect the starting of data nodes—including --initial-start, --nostart, and --nowait-nodes— together with --install, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The --install option has no effect on non-Windows platforms.

• --logbuffer-size=#

Command-Line Format: --logbuffer-size=#

Type: Integer

Default Value: 32768

Minimum Value: 2048

Maximum Value: 4294967295

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

• --login-path

Command-Line Format: --login-path=path

Type: String

Default Value: [none]

Read given path from login file.
- **--no-login-paths**

  **Command-Line Format**
  
  ```
  --no-login-paths
  ```

  Skips reading options from the login path file.

- **--ndb-connectstring**

  **Command-Line Format**
  
  ```
  --ndb-connectstring=connection_string
  ```

  **Type**
  
  String

  **Default Value**
  
  [none]

  Set connection string for connecting to ndb_mgmd. Syntax: 
  ```
  [nodeid=id;]
  [host=]hostname[:port].
  ```

  Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **--ndb-mgmd-host**

  **Command-Line Format**
  
  ```
  --ndb-mgmd-host=connection_string
  ```

  **Type**
  
  String

  **Default Value**
  
  [none]

  Same as **--ndb-connectstring**.

- **--ndb-mgm-tls**

  **Command-Line Format**
  
  ```
  --ndb-mgm-tls=level
  ```

  **Type**
  
  Enumeration

  **Default Value**
  
  relaxed

  **Valid Values**
  
  relaxed

  strict

  Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

- **--ndb-nodeid**

  **Command-Line Format**
  
  ```
  --ndb-nodeid=#
  ```

  **Type**
  
  Integer

  **Default Value**
  
  [none]

  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--ndb-optimized-node-selection**

  **Command-Line Format**
  
  ```
  --ndb-optimized-node-selection
  ```

  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

- **--ndb-tls-search-path**

  **Command-Line Format**
  
  ```
  --ndb-tls-search-path=list
  ```

  **Type**
  
  Path name
Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:) on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using -DWITH_NDB_TLS_SEARCH_PATH.

• **--nodaemon**

Prevents ndbd or ndbmd from executing as a daemon process. This option overrides the --daemon option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for ndbd and ndbmd on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

• **--no-defaults**

Do not read default options from any option file other than login file.

• **--nostart, -n**

Instructs ndbd not to start automatically. When this option is used, ndbd connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper START command in the management client (see Section 25.6.1, “Commands in the NDB Cluster Management Client”).

• **--nowait-nodes=node_id_1[, node_id_2[, ...]]**

This option takes a list of data nodes for which the cluster does not wait, prior to starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each ndbd process with --nowait-nodes=3,5. In this case, the cluster starts as soon as nodes 2 and 4...
connect, and does not wait \texttt{StartPartitionedTimeout} milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one \texttt{ndbd} (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with \texttt{--nowait-nodes=3}. Then the cluster starts as soon as nodes 2, 4, and 5 connect, and does not wait for node 3 to start.

\begin{itemize}
  \item \texttt{--print-defaults} \\
  \textbf{Command-Line Format} \hfill \texttt{--print-defaults} \\
  \text{Print program argument list and exit.}

  \item \texttt{--remove[=name]} \\
  \textbf{Command-Line Format} \hfill \texttt{--remove[=name]} \\
  \textbf{Platform Specific} \hfill \text{Windows} \\
  \textbf{Type} \hfill \text{String} \\
  \textbf{Default Value} \hfill \texttt{ndbd} \\
  \text{Causes an \texttt{ndbd} process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to \texttt{ndbd}.}

  The \texttt{--remove} option has no effect on non-Windows platforms.

  \item \texttt{--usage} \\
  \textbf{Command-Line Format} \hfill \texttt{--usage} \\
  \text{Display help text and exit; same as \texttt{--help}.}

  \item \texttt{--verbose, -v} \\
  \text{Causes extra debug output to be written to the node log.}

  You can also use \texttt{NODELOG DEBUG ON} and \texttt{NODELOG DEBUG OFF} to enable and disable this extra logging while the data node is running.

  \item \texttt{--version} \\
  \textbf{Command-Line Format} \hfill \texttt{--version} \\
  \text{Display version information and exit.}
\end{itemize}

\texttt{ndbd} generates a set of log files which are placed in the directory specified by \texttt{DataDir} in the \texttt{config.ini} configuration file.

These log files are listed below. \texttt{node_id} is and represents the node's unique identifier. For example, \texttt{ndb_2_error.log} is the error log generated by the data node whose node ID is 2.

\begin{itemize}
  \item \texttt{ndb\_node_id\_error.log} is a file containing records of all crashes which the referenced \texttt{ndbd} process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

\begin{verbatim}
Date/Time: Saturday 30 July 2004 - 00:20:01 
Type of error: error 
Message: Internal program error (failed ndbrequire) 
Fault ID: 2341
\end{verbatim}
\end{itemize}
Lists of possible ndbd exit codes and messages generated when a data node process shuts down prematurely can be found in Data Node Error Messages.

Important

The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the ndb_node_id_trace.log.next file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- ndb_node_id_trace.log.trace_id is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that are created before old files are overwritten. trace_id is a number which is incremented for each successive trace file.

- ndb_node_id_trace.log.next is the file that keeps track of the next trace file number to be assigned.

- ndb_node_id_out.log is a file containing any data output by the ndbd process. This file is created only if ndbd is started as a daemon, which is the default behavior.

- ndb_node_id.pid is a file containing the process ID of the ndbd process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- ndb_node_id_signal.log is a file used only in debug versions of ndbd, where it is possible to trace all incoming, outgoing, and internal messages with their data in the ndbd process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the .pid file remains in effect even after the process has terminated.

To start ndbd, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

$> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"

See Section 25.4.3.3, “NDB Cluster Connection Strings”, for additional information about this issue. For more information about data node configuration parameters, see Section 25.4.3.6, “Defining NDB Cluster Data Nodes”.

When ndbd starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the ndbd process if it is configured to do so. Thus, if you attempt to kill ndbd using the Unix kill command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an ndbd process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the ndbd process. In a multi-processor system performing a large number of operations (including updates), the ndbd process can consume up to 2 CPUs if permitted to do so.
For a machine with many CPUs it is possible to use several ndbd processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 8.4 in a production setting. See Section 25.2.7, "Known Limitations of NDB Cluster".

25.5.2 ndbinfo_select_all — Select From ndbinfo Tables

ndbinfo_select_all is a client program that selects all rows and columns from one or more tables in the ndbinfo database.

Not all ndbinfo tables available in the mysql client can be read by this program (see later in this section). In addition, ndbinfo_select_all can show information about some tables internal to ndbinfo which cannot be accessed using SQL, including the tables and columns metadata tables.

To select from one or more ndbinfo tables using ndbinfo_select_all, it is necessary to supply the names of the tables when invoking the program as shown here:

```
$> ndbinfo_select_all table_name1 [table_name2] ...
```

For example:

```bash
$> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type log_id log_part total used high
5   0   0   0       33554432 262144 0
6   0   0   0       33554432 262144 0
7   0   0   0       33554432 262144 0
8   0   0   0       33554432 262144 0
== logspaces ==
node_id log_type log_id log_part total used high
5   0   0   0       268435456 0 0
5   0   0   1       268435456 0 0
5   0   0   2       268435456 0 0
5   0   0   3       268435456 0 0
6   0   0   0       268435456 0 0
6   0   0   1       268435456 0 0
6   0   0   2       268435456 0 0
6   0   0   3       268435456 0 0
7   0   0   0       268435456 0 0
7   0   0   1       268435456 0 0
7   0   0   2       268435456 0 0
7   0   0   3       268435456 0 0
8   0   0   0       268435456 0 0
8   0   0   1       268435456 0 0
8   0   0   2       268435456 0 0
8   0   0   3       268435456 0 0
$>
```

Options that can be used with ndbinfo_select_all are shown in the following table. Additional descriptions follow the table.

* --character-sets-dir

Command-Line Format  
```
--character-sets-dir=path
```
Directory containing character sets.

* --core-file

Command-Line Format  
```
--core-file
```
Write core file on error; used in debugging.

* --connect-retries

Command-Line Format  
```
--connect-retries=#
```
ndbinfo_select_all — Select From ndbinfo Tables

</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

• **--defaults-file**

Command-Line Format  
`--defaults-file=path`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read default options from given file only.

• **--defaults-group-suffix**

Command-Line Format  
`--defaults-group-suffix=string`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with concat(group, suffix).

• **--delay=seconds**

Command-Line Format  
`--delay=#`

<table>
<thead>
<tr>
<th>Type</th>
<th>Numeric</th>
</tr>
</thead>
</table>
ndbinfo_select_all — Select From ndbinfo Tables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>0</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

This option sets the number of seconds to wait between executing loops. Has no effect if --loops is set to 0 or 1.

- **--help**
  
  Command-Line Format: `--help`

  Display help text and exit.

- **--login-path**
  
  Command-Line Format: `--login-path=path`

  Type: String

  Default Value: [none]

  Read given path from login file.

- **--no-login-paths**
  
  Command-Line Format: `--no-login-paths`

  Skips reading options from the login path file.

- **--loops=number, -l number**
  
  Command-Line Format: `--loops=#`

  Type: Numeric

  Default Value: 1

  Minimum Value: 0

  Maximum Value: MAX_INT

  This option sets the number of times to execute the select. Use --delay to set the time between loops.

- **--ndb-connectstring**
  
  Command-Line Format: `--ndb-connectstring=connection-string`

  Type: String

  Default Value: [none]

  Set connection string for connecting to ndb_mgmd. Syntax: [nodeid=id;] [host=]hostname[:port]. Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **--ndb-mgmd-host**
  
  Command-Line Format: `--ndb-mgmd-host=connection-string`

  Type: String

  Default Value: [none]

  Same as --ndb-connectstring.
• **--ndb-nodeid**

  **Command-Line Format**
  
  
  --ndb-nodeid=#

  **Type**
  
  Integer

  **Default Value**
  
  [none]

  Set node ID for this node, overriding any ID set by --ndb-connectstring.

• **--ndb-optimized-node-selection**

  **Command-Line Format**
  
  --ndb-optimized-node-selection

  Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

• **--no-defaults**

  **Command-Line Format**
  
  --no-defaults

  Do not read default options from any option file other than login file.

• **--print-defaults**

  **Command-Line Format**
  
  --print-defaults

  Print program argument list and exit.

• **--usage**

  **Command-Line Format**
  
  --usage

  Display help text and exit; same as --help.

• **--version**

  **Command-Line Format**
  
  --version

  Display version information and exit.

**ndbinfo_select_all** is unable to read the following tables:

25.5.3 ndbmt — The NDB Cluster Data Node Daemon (Multi-Threaded)

`ndbmt` is a multithreaded version of `ndbd`, the process that is used to handle all the data in tables using the NDBCLUSTER storage engine. `ndbmt` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmt` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmt` differs from `ndbd`, and you should consult Section 25.5.1, “ndbd — The NDB Cluster Data Node Daemon”, for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmt`. For more information about these options and parameters, see Section 25.5.1, “ndbd — The NDB Cluster Data Node Daemon”, and Section 25.4.3.6, “Defining NDB Cluster Data Nodes”, respectively.

`ndbmt` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmt`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value before restarting the node if you wish for `ndbmt` to run in multithreaded fashion.) Similarly, an `ndbmt` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Using `ndbmt` differs from using `ndbd` in two key respects:

1. Because `ndbmt` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter or the `ThreadConfig` configuration parameter. Using `MaxNoOfExecutionThreads` is simpler, but `ThreadConfig` offers more flexibility. For more information about these configuration parameters and their use, see Multi-Threading Configuration Parameters (ndbmt).

2. Trace files are generated by critical errors in `ndbmt` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmt` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmt` generates trace files describing what happened just prior to the error occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmt` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_thread_id,
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmt` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If the is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.
The *ndbd* exit codes and messages that are generated when a data node process shuts down prematurely are also used by *ndbmtd*. See Data Node Error Messages, for a listing of these.

**Note**

It is possible to use *ndbd* and *ndbmtd* concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

### 25.5.4 ndb_mgmd — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

All options that can be used with *ndb_mgmd* are shown in the following table. Additional descriptions follow the table.

- **--bind-address=host**
  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bind-address=host</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

- **--character-sets-dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-sets-dir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Directory containing character sets.</td>
<td></td>
</tr>
</tbody>
</table>

- **--cluster-config-suffix**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--cluster-config-suffix=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Override defaults group suffix when reading cluster configuration sections in *my.cnf*; used in testing.

- **--config-cache**

  | Command-Line Format | --config-cache[=TRUE|FALSE] |
  |--------------------|-----------------------------|
  | Type               | Boolean                     |
  | Default Value      | TRUE                        |

This option, whose default value is 1 (or TRUE, or ON), can be used to disable the management server's configuration cache, so that it reads its configuration from *config.ini* every time it starts (see Section 25.4.3, "NDB Cluster Configuration Files"). You can do this by starting the *ndb_mgmd* process with any one of the following options:

- **--config-cache=0**
- **--config-cache=FALSE**
• `--config-cache=OFF`

• `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the first time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has already created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

`ndb_node-id_config.bin.seq-number`

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

`ndb_mgmd` does not check for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

• `--config-file=filename, -f filename`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--config-file=file</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled by</td>
<td><code>skip-config-file</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. If `--config-file` is specified without either of `--initial` or `--reload`, `ndb_mgmd` refuses to start.

The `--config-file` option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See Section 25.4.3, "NDB Cluster Configuration Files", for more information.

• `--configdir=dir_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--configdir=directory</code></th>
</tr>
</thead>
</table>

4079
### --config-dir=directory

**Type**: File name  
**Default Value**: $INSTALLDIR/mysql-cluster

Specifies the cluster management server’s configuration cache directory. This must be an absolute path. Otherwise, the management server refuses to start.  

--config-dir is an alias for this option.

### --connect-retries

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>12</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>12</td>
</tr>
</tbody>
</table>

Number of times to retry connection before giving up.

### --connect-retry-delay

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retry-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>5</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

### --connect-string

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-string=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as --ndb-connectstring.

### --core-file

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--core-file</th>
</tr>
</thead>
</table>

Write core file on error; used in debugging.

### --daemon, -d

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon</th>
</tr>
</thead>
</table>

Instructs ndb_mgmd to start as a daemon process. This is the default behavior.  

This option has no effect when running ndb_mgmd on Windows platforms.

### --defaults-extra-file

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-extra-file=path</th>
</tr>
</thead>
</table>
**ndb_mgmd — The NDB Cluster Management Server Daemon**

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

- **--defaults-file**

  **Command-Line Format**

  ```
  --defaults-file=path
  ```

  **Type** String

  **Default Value** [none]

  Read default options from given file only.

- **--defaults-group-suffix**

  **Command-Line Format**

  ```
  --defaults-group-suffix=string
  ```

  **Type** String

  **Default Value** [none]

  Also read groups with concat(group, suffix).

- **--help**

  **Command-Line Format**

  ```
  --help
  ```

  Display help text and exit.

- **--initial**

  **Command-Line Format**

  ```
  --initial
  ```

  Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see Section 25.4.3, “NDB Cluster Configuration Files”). Using the **--initial** option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

  This differs in two ways from the **--reload** option. First, **--reload** forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, **--reload** does not delete any existing cache files.

  If `ndb_mgmd` is invoked with **--initial** but cannot find a global configuration file, the management server cannot start.

  When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

  When used together with the **--config-file** option, the cache is cleared only if the configuration file is actually found.

- **--install[=name]**

  **Command-Line Format**

  ```
  --install[=name]
  ```

  **Platform Specific** Windows

  **Type** String
Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- **--interactive**

  Command-Line Format  
  
  ```
  --interactive
  ```

  Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- **--log-name=name**

  Command-Line Format  
  
  ```
  --log-name=name
  ```

  Type  
  String

  Default Value  
  MgmtSrvr

  Provides a name to be used for this node in the cluster log.

- **--login-path**

  Command-Line Format  
  
  ```
  --login-path=path
  ```

  Type  
  String

  Default Value  
  [none]

  Read given path from login file.

- **--no-login-paths**

  Command-Line Format  
  
  ```
  --no-login-paths
  ```

  Skips reading options from the login path file.

- **--mycnf**

  Command-Line Format  
  
  ```
  --mycnf
  ```

  Read configuration data from the `my.cnf` file.

- **--ndb-connectstring**

  Command-Line Format  
  
  ```
  --ndb-connectstring=connection_string
  ```

  Type  
  String

  Default Value  
  [none]
Set connection string. Syntax: [nodeid=]id;[host=]hostname[:port]. Overrides entries in NDB_CONNECTSTRING and my.cnf. Ignored if --config-file is specified; a warning is issued if both options are used concurrently.

- --ndb-mgm-tls

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-mgm-tls=level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>relaxed</td>
</tr>
<tr>
<td>Valid Values</td>
<td>relaxed strict</td>
</tr>
</tbody>
</table>

Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

- --ndb-mgmd-host

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-mgmd-host=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as --ndb-connectstring.

- --ndb-nodeid

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodeid=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Set node ID for this node, overriding any ID set by --ndb-connectstring.

- --ndb-optimized-node-selection

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-optimized-node-selection</th>
</tr>
</thead>
</table>

Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

- --ndb-tls-search-path

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-tls-search-path=list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Path name</td>
</tr>
<tr>
<td>Default Value (Unix)</td>
<td>$HOME/ndb-tls</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td>$HOMEDIR/ndb-tls</td>
</tr>
</tbody>
</table>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.
If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- **--no-nodeid-checks**

  Command-Line Format `--no-nodeid-checks`

  Do not perform any checks of node IDs.

- **--nodaemon**

  Command-Line Format `--nodaemon`

  Instructs `ndb_mgmd` not to start as a daemon process.

  The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- **--no-defaults**

  Command-Line Format `--no-defaults`

  Do not read default options from any option file other than login file.

- **--nowait-nodes**

  Command-Line Format `--nowait-nodes=list`

  Type Numeric

  Default Value [none]

  Minimum Value 1

  Maximum Value 255

  When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

  For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

  ```ini
  [ndbd]
  NodeId = 1
  HostName = 198.51.100.101
  
  [ndbd]
  NodeId = 2
  HostName = 198.51.100.102
  
  [ndbd]
  NodeId = 3
  HostName = 198.51.100.103
  
  [ndbd]
  NodeId = 4
  HostName = 198.51.100.104
  ```
Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to let the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
$> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster’s data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
$> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See Section 25.4.3.3, “NDB Cluster Connection Strings”, for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtd` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

---

### Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

---

```
--print-defaults
```

Print program argument list and exit.
ndb_mgmd — The NDB Cluster Management Server Daemon

• **--print-full-config, -P**

**Command-Line Format**

```
--print-full-config
```

Shows extended information regarding the configuration of the cluster. With this option on the command line the ndb_mgmd process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the **--config-file** (-f) option.

• **--reload**

**Command-Line Format**

```
--reload
```

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 25.4.3, “NDB Cluster Configuration Files”). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the **--initial** option. First, **--initial** causes all cache files to be deleted. Second, **--initial** forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the **--reload** option is ignored.

When **--reload** is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use **--initial** instead to force the existing cached configuration to be discarded and reloaded from the file. See Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”, for additional information.

• **--remove[=name]**

**Command-Line Format**

```
--remove[=name]
```

**Platform Specific**

Windows

**Type**

String

**Default Value**

ndb_mgmd

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

• **--skip-config-file**

**Command-Line Format**

```
--skip-config-file
```

Do not read cluster configuration file; ignore **--initial** and **--reload** options if specified.

• **--usage**

**Command-Line Format**

```
--usage
```

Display help text and exit; same as **--help**.
• **--verbose, -v**

**Command-Line Format**  
--verbose

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

• **--version**

**Command-Line Format**  
--version

Display version information and exit.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 25.4.3.3, “NDB Cluster Connection Strings”, for information about using connection strings. Section 25.5.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, describes other options for ndb_mgmd.

The following files are created or used by ndb_mgmd in its starting directory, and are placed in the DataDir as specified in the config.ini configuration file. In the list that follows, node_id is the unique node identifier.

• **config.ini** is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 25.4, “Configuration of NDB Cluster”, discusses how to set up this file.

• **ndb_node_id_cluster.log** is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 25.6, “Management of NDB Cluster”.

By default, when the size of the cluster log reaches one million bytes, the file is renamed to ndb_node_id_cluster.log.seq_id, where seq_id is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the LogDestination configuration parameter.

• **ndb_node_id_out.log** is the file used for stdout and stderr when running the management server as a daemon.

• **ndb_node_id.pid** is the process ID file used when running the management server as a daemon.

### 25.5.5 ndb_mgm — The NDB Cluster Management Client

The ndb_mgm management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster’s status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by ndb_mgm.

To start the management client, it is necessary to supply the host name and port number of the management server:

```bash
$> ndb_mgm [host_name [port_num]]
```

For example:

```bash
$> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are localhost and 1186, respectively.
All options that can be used with `ndb_mgm` are shown in the following table. Additional descriptions follow the table.

- **--backup-password-from-stdin[=TRUE|FALSE]**

  **Command-Line Format**
  --backup-password-from-stdin

  This option enables input of the backup password from the system shell (`stdin`) when using `--execute "START BACKUP"` or similar to create a backup. Use of this option requires use of `--execute` as well.

- **--character-sets-dir**

  **Command-Line Format**
  --character-sets-dir=path

  Directory containing character sets.

- **--connect-retries=#**

  **Command-Line Format**
  --connect-retries=#

  **Type**
  Numeric

  **Default Value**
  3

  **Minimum Value**
  0

  **Maximum Value**
  4294967295

  This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

  This option is synonymous with the `--try-reconnect` option, which is now deprecated.

- **--connect-retry-delay**

  **Command-Line Format**
  --connect-retry-delay=#

  **Type**
  Integer

  **Default Value**
  5

  **Minimum Value**
  0

  **Maximum Value**
  5

  Number of seconds to wait between attempts to contact management server.

- **--connect-string**

  **Command-Line Format**
  --connect-string=connection_string

  **Type**
  String

  **Default Value**
  [none]

  Same as `--ndb-connectstring`.

- **--core-file**

  **Command-Line Format**
  --core-file

  Write core file on error; used in debugging.
---

**--defaults-extra-file**

**Command-Line Format**

```
--defaults-extra-file=path
```

**Type**

String

**Default Value**

[none]

Read given file after global files are read.

**--defaults-file**

**Command-Line Format**

```
--defaults-file=path
```

**Type**

String

**Default Value**

[none]

Read default options from given file only.

**--defaults-group-suffix**

**Command-Line Format**

```
--defaults-group-suffix=string
```

**Type**

String

**Default Value**

[none]

Also read groups with concat(group, suffix).

**--encrypt-backup**

**Command-Line Format**

```
--encrypt-backup
```

When used, this option causes all backups to be encrypted. To make this happen whenever `ndb_mgm` is run, put the option in the `ndb_mgm` section of the `my.cnf` file.

**--execute=command, -e command**

**Command-Line Format**

```
--execute=command
```

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
$> ndb_mgm -e "SHOW"
$> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See Section 6.2.2.1, "Using Options on the Command Line".

---

**Note**

If the management client command to be passed using this option contains any space characters, then the command must be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

**--help**

**Command-Line Format**

```
--help
```

Display help text and exit.
- **--login-path**

  **Command-Line Format**
  ```
  --login-path=path
  ```

  **Type** String

  **Default Value** [none]

  Read given path from login file.

- **--no-login-paths**

  **Command-Line Format**
  ```
  --no-login-paths
  ```

  Skips reading options from the login path file.

- **--ndb-connectstring**

  **Command-Line Format**
  ```
  --ndb-connectstring=connection_string
  ```

  **Type** String

  **Default Value** [none]

- **--ndb-nodeid**

  **Command-Line Format**
  ```
  --ndb-nodeid=#
  ```

  **Type** Integer

  **Default Value** [none]

  Set node ID for this node, overriding any ID set by --ndb-connectstring.

- **--ndb-mgm-tls**

  **Command-Line Format**
  ```
  --ndb-mgm-tls=level
  ```

  **Type** Enumeration

  **Default Value** relaxed

  **Valid Values** relaxed, strict

  Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

- **--ndb-mgmd-host**

  **Command-Line Format**
  ```
  --ndb-mgmd-host=connection_string
  ```

  **Type** String

  **Default Value** [none]

  Same as --ndb-connectstring.
- **--ndb-optimized-node-selection**
  
  Command-Line Format: **--ndb-optimized-node-selection**
  
  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

- **--ndb-tls-search-path**
  
  Command-Line Format: **--ndb-tls-search-path=list**
  
<table>
<thead>
<tr>
<th>Type</th>
<th>Path name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value (Unix)</td>
<td>$HOME/ndb-tls</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td>$HOMEDIR/ndb-tls</td>
</tr>
</tbody>
</table>
  
  Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

  Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path is limited to the current working directory.

  If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using -DWITH_NDB_TLS_SEARCH_PATH.

- **--no-defaults**
  
  Command-Line Format: **--no-defaults**
  
  Do not read default options from any option file other than login file.

- **--print-defaults**
  
  Command-Line Format: **--print-defaults**
  
  Print program argument list and exit.

- **--test-tls**
  
  Command-Line Format: **--test-tls**
  
  Connect using TLS, then exit. Output if successful is similar to what is shown here:

  ```bash
  >$ ndb_mgm --test-tls
  Connected to Management Server at: sakila:1186
  >$
  
  See Section 25.6.15, “TLS Link Encryption for NDB Cluster”, for more information.

- **--try-reconnect=number**
  
  Command-Line Format: **--try-reconnect=#**
  
  | Deprecated | Yes |
  | Type       | Numeric |
  | Type       | Integer |
ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to number before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use --connect-retries, instead.

- --usage

Command-Line Format

```
--usage
```

Display help text and exit; same as --help.

- --version

Command-Line Format

```
--version
```

Display version information and exit.

Additional information about using ndb_mgm can be found in Section 25.6.1, “Commands in the NDB Cluster Management Client”.

25.5.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.

The basic syntax for ndb_blob_tool is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the --help option, you must specify an action to be performed by including one or more of the options --check-orphans, --delete-orphans, or --dump-file. These options cause ndb_blob_tool to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking ndb_blob_tool. In addition, you can optionally follow the table name with the (comma-separated) names of one or more BLOB or TEXT columns from that table. If no columns are listed, the tool works on all of the table's BLOB and TEXT columns. If you need to specify a database, use the --database (-d) option.

The --verbose option provides additional information in the output about the tool's progress.

All options that can be used with ndb_mgmd are shown in the following table. Additional descriptions follow the table.

- --add-missing

Command-Line Format

```
--add-missing
```

4092
For each inline part in NDB Cluster tables which has no corresponding BLOB part, write a dummy BLOB part of the required length, consisting of spaces.

- **--character-sets-dir**

  Command-Line Format

  --character-sets-dir=path

  Directory containing character sets.

- **--check-missing**

  Command-Line Format

  --check-missing

  Check for inline parts in NDB Cluster tables which have no corresponding BLOB parts.

- **--check-orphans**

  Command-Line Format

  --check-orphans

  Check for BLOB parts in NDB Cluster tables which have no corresponding inline parts.

- **--connect-retries**

  Command-Line Format

  --connect-retries=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

  Number of times to retry connection before giving up.

- **--connect-retry-delay**

  Command-Line Format

  --connect-retry-delay=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

  Number of seconds to wait between attempts to contact management server.

- **--connect-string**

  Command-Line Format

  --connect-string=connection_string

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

  Same as **--ndb-connectstring**.

- **--core-file**

  Command-Line Format

  --core-file

  Write core file on error; used in debugging.
ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

- **--database=db_name, -d**
  
  **Command-Line Format**
  
  --database=name

  **Type**
  
  String

  **Default Value**
  
  [none]

  Specify the database to find the table in.

- **--defaults-extra-file**
  
  **Command-Line Format**
  
  --defaults-extra-file=path

  **Type**
  
  String

  **Default Value**
  
  [none]

  Read given file after global files are read.

- **--defaults-file**
  
  **Command-Line Format**
  
  --defaults-file=path

  **Type**
  
  String

  **Default Value**
  
  [none]

  Read default options from given file only.

- **--defaults-group-suffix**
  
  **Command-Line Format**
  
  --defaults-group-suffix=string

  **Type**
  
  String

  **Default Value**
  
  [none]

  Also read groups with concat(group, suffix).

- **--delete-orphans**
  
  **Command-Line Format**
  
  --delete-orphans

  Remove BLOB parts from NDB Cluster tables which have no corresponding inline parts.

- **--dump-file=file**
  
  **Command-Line Format**
  
  --dump-file=file

  **Type**
  
  File name

  **Default Value**
  
  [none]

  Writes a list of orphaned BLOB column parts to file. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- **--help**
  
  **Command-Line Format**
  
  --help

  Display help text and exit.

- **--login-path**
  
  **Command-Line Format**
  
  --login-path=path
### ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

<table>
<thead>
<tr>
<th>Type</th>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Command-Line Format**

- **--no-login-paths**
- **--ndb-connectstring**
- **--ndb-mgm-tls=level**
- **--ndb-mgmd-host=connection_string**
- **--ndb-nodeid=#**
- **--ndb-optimized-node-selection**
• **--ndb-tls-search-path**

Command-Line Format

```
--ndb-tls-search-path=list
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Path name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value (Unix)</td>
<td>$HOME/ndb-tls</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td>$HOMEDIR/ndb-tls</td>
</tr>
</tbody>
</table>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:) ; on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

• **--no-defaults**

Command-Line Format

```
--no-defaults
```

Do not read default options from any option file other than login file.

• **--print-defaults**

Command-Line Format

```
--print-defaults
```

Print program argument list and exit.

• **--usage**

Command-Line Format

```
--usage
```

Display help text and exit; same as --help.

• **--verbose**

Command-Line Format

```
--verbose
```

Provide extra information in the tool’s output regarding its progress.

• **--version**

Command-Line Format

```
--version
```

Display version information and exit.

### Example

First we create an NDB table in the test database, using the `CREATE TABLE` statement shown here:

```
USE test;
CREATE TABLE btest (  
c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
c1 TEXT,
```
Then we insert a few rows into this table, using a series of statements similar to this one:

```sql
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, `ndb_blob_tool` generates the following output:

```bash
$> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected
```

The tool reports that there are no NDB BLOB column parts associated with column `c1`, even though `c1` is a TEXT column. This is due to the fact that, in an NDB table, only the first 256 bytes of a BLOB or TEXT column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no BLOB column parts are created by NDB for this column. See Section 13.7, “Data Type Storage Requirements”, for more information.

25.5.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its config.ini or my.cnf file. By default, the management node is the source for the configuration data; to override the default, execute `ndb_config` with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=node_id`.

`ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

You can filter the results by section (DB, SYSTEM, or CONNECTIONS) using one of the options `--nodes`, `--system`, or `--connections`.

All options that can be used with `ndb_config` are shown in the following table. Additional descriptions follow the table.

- **--character-sets-dir**
  
  Command-Line Format
  
  ```bash
  --character-sets-dir=path
  ```

  Directory containing character sets.

- **cluster-config-suffix**
ndb_config — Extract NDB Cluster Configuration Information

Command-Line Format

<table>
<thead>
<tr>
<th>Type</th>
<th>--cluster-config-suffix=name</th>
</tr>
</thead>
</table>

Type | String
Default Value | [none]

Override defaults group suffix when reading cluster configuration sections in `my.cnf`; used in testing.

• **--configinfo**

The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

• A brief description of each parameter's purpose, effects, and usage
• The section of the `config.ini` file where the parameter may be used
• The parameter's data type or unit of measurement
• Where applicable, the parameter's default, minimum, and maximum values
• NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```bash
$> ndb_config --configinfo

****** SYSTEM ******
Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

****** DB ******
MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)
```

Use this option together with the `--xml` option to obtain output in XML format.

• **--config-binary-file=path/to/file**

Command-Line Format

<table>
<thead>
<tr>
<th>Type</th>
<th>--config-binary-file=path/to/file</th>
</tr>
</thead>
</table>

Type | File name
Default Value

Gives the path to the management server's cached binary configuration file (`ndb_nodeID_config.bin.seqno`). This may be a relative or absolute path. If the management server and the `ndb_config` binary used reside on different hosts, you must use an absolute path.

This example demonstrates combining `--config-binary-file` with other `ndb_config` options to obtain useful output:

```bash
$> ndb_config --config-binary-file=../mysql-cluster/ndb_50_config.bin.1 --diff-default --system
```

config of [DB] node id 5 that is different from default

<table>
<thead>
<tr>

</tr>
<tr>
<td>FileSystemPath</td>
<td>/local/data/8.4</td>
<td>(null)</td>
</tr>
<tr>
<td>HostName</td>
<td>127.0.0.1</td>
<td>localhost</td>
</tr>
<tr>
<td>Nodegroup</td>
<td>0</td>
<td>(null)</td>
</tr>
<tr>
<td>ThreadConfig</td>
<td>, (null)</td>
<td></td>
</tr>
</tbody>
</table>

$>
```

config of [SYSTEM] system

<table>
<thead>
<tr>
<th>CONFIG_PARAMETER</th>
<th>ACTUAL_VALUE</th>
<th>DEFAULT_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>MC_2022090600042</td>
<td>(mandatory)</td>
</tr>
<tr>
<td>ConfigGenerationNumber</td>
<td>1,0</td>
<td></td>
</tr>
<tr>
<td>PrimaryMGMNode</td>
<td>50</td>
<td>0</td>
</tr>
</tbody>
</table>

The relevant portions of the `config.ini` file are shown here:

```ini
[nmdb default]
DataMemory= 2G
NoOfReplicas= 2

[nmdb_mgmd]
NodeId= 50
HostName= 127.0.0.1

[nmdb]
NodeId= 5
HostName= 127.0.0.1
DataDir= /local/data/8.4

[nmdb]
NodeId= 6
HostName= 127.0.0.1
DataDir= /local/data/8.4
```

By comparing the output with the configuration file, you can see that all of the settings in the file have been written by the management server to the binary cache, and thus, applied to the cluster.

• `--config-file=path-to-file`

---

**Command-Line Format**

<table>
<thead>
<tr>
<th>Type</th>
<th>--config-file=file_name</th>
</tr>
</thead>
</table>

4099
ndb_config — Extract NDB Cluster Configuration Information

Default Value

Gives the path to the cluster configuration file (config.ini). This may be a relative or absolute path. If the management server and the ndb_config binary used reside on different hosts, you must use an absolute path.

• **--config-from-node=**#

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--config-from-node=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>48</td>
</tr>
</tbody>
</table>

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, ndb_config fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

• **--connect-retries**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retries=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

Number of times to retry connection before giving up.

• **--connect-retry-delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retry-delay=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

• **--connect-string**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-string=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as **--ndb-connectstring**.

• **--connections**

Tells ndb_config to print CONNECTIONS information only—that is, information about parameters found in the [tcp], [tcp default], [shm], or [shm default] sections of the cluster.
configuration file (see Section 25.4.3.10, “NDB Cluster TCP/IP Connections”, and Section 25.4.3.12, “NDB Cluster Shared-Memory Connections”, for more information).

This option is mutually exclusive with --nodes and --system; only one of these 3 options can be used.

- --core-file

Command-Line Format    --core-file
Write core file on error; used in debugging.

- --defaults-extra-file

Command-Line Format    --defaults-extra-file=path
Type                   String
Default Value          [none]
Read given file after global files are read.

- --defaults-file

Command-Line Format    --defaults-file=path
Type                   String
Default Value          [none]
Read default options from given file only.

- --defaults-group-suffix

Command-Line Format    --defaults-group-suffix=string
Type                   String
Default Value          [none]
Also read groups with concat(group, suffix).

- --diff-default

Command-Line Format    --diff-default
Print only configuration parameters that have non-default values.

- --fields=delimiter, -f delimiter

Command-Line Format    --fields=string
Type                   String
Default Value
Specifies a delimiter string used to separate the fields in the result. The default is , (the comma character).

Note

If the delimiter contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- --help
ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--help</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display help text and exit.</td>
<td></td>
</tr>
</tbody>
</table>

- **--host=hostname**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--host=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the host name of the node for which configuration information is to be obtained.

**Note**

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- **--login-path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--login-path=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given path from login file.

- **--mycnf**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mycnf</th>
</tr>
</thead>
</table>

Read configuration data from the `my.cnf` file.

- **--ndb-connectstring=connection_string, -c connection_string**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-connectstring=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 25.4.3.3, “NDB Cluster Connection Strings”, and defaults to `localhost:1186`.

- **--ndb-mgm-tls**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-mgm-tls=level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>relaxed</td>
</tr>
<tr>
<td>Valid Values</td>
<td>relaxed</td>
</tr>
</tbody>
</table>
**strict**

Sets the level of TLS support required to connect to the management server; one of *relaxed* or *strict*.*relaxed* (the default) means that a TLS connection is attempted, but success is not required; *strict* means that TLS is required to connect.

- **--ndb-mgmd-host**

  | Command-Line Format | --ndb-mgmd-host=connection_string |
  | Type               | String                           |
  | Default Value      | [none]                           |

  Same as **--ndb-connectstring**.

- **--ndb-nodeid**

  | Command-Line Format | --ndb-nodeid=# |
  | Type               | Integer        |
  | Default Value      | [none]         |

  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--ndb-optimized-node-selection**

  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

- **--ndb-tls-search-path**

  | Command-Line Format | --ndb-tls-search-path=list |
  | Type               | Path name                |
  | Default Value (Unix) | $HOME/ndb-tls          |
  | Default Value (Windows) | $HOMEDIR/ndb-tls   |

  Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

  Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

  If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using **-DWITH_NDB_TLS_SEARCH_PATH**.

- **--no-defaults**

  | Command-Line Format | --no-defaults |
  | Do not read default options from any option file other than login file. |
ndb_config — Extract NDB Cluster Configuration Information

- **--no-login-paths**

  Command-Line Format: **--no-login-paths**

  Skips reading options from the login path file.

- **--nodeid=node_id**

  Command-Line Format: **--ndb-nodeid=#**

  Type: Integer

  Default Value: [none]

  Specify the node ID of the node for which configuration information is to be obtained.

- **--nodes**

  Command-Line Format: **--nodes**

  Tells ndb_config to print information relating only to parameters defined in an [ndbd] or [ndbd default] section of the cluster configuration file (see Section 25.4.3.6, “Defining NDB Cluster Data Nodes”).

  This option is mutually exclusive with --connections and --system; only one of these 3 options can be used.

- **--print-defaults**

  Command-Line Format: **--print-defaults**

  Print program argument list and exit.

- **--query=query-options, -q query-options**

  Command-Line Format: **--query=string**

  Type: String

  This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include nodeid (node ID), type (node type—that is, ndbd, mysqld, or ndb_mgmd), and any configuration parameters whose values are to be obtained.

  For example, **--query=nodeid,type,datamemory,datadir** returns the node ID, node type, DataMemory, and DataDir for each node.

  **Note**

  If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- **--query-all, -a**

  Command-Line Format: **--query-all**

  Type: String
ndb_config — Extract NDB Cluster Configuration Information

Default Value

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string).

• **--rows=separator, -r separator**

  Command-Line Format
  
  **--rows=string**

  Type
  
  String

  Default Value

  Specifies a separator string used to separate the rows in the result. The default is a space character.

  **Note**
  
  If the separator contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

• **--system**

  Command-Line Format
  
  **--system**

  Tells ndb_config to print SYSTEM information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with ****** SYSTEM ******) in the output of ndb_config --configinfo.

  This option is mutually exclusive with --nodes and --connections; only one of these 3 options can be used.

• **--type=node_type**

  Command-Line Format
  
  **--type=name**

  Type
  
  Enumeration

  Default Value
  
  [none]

  Valid Values
  
  ndbd
  
  mysqlld
  
  ndb_mgmd

  Filters results so that only configuration values applying to nodes of the specified node_type (ndbd, mysqlld, or ndb_mgmd) are returned.

• **--usage, --help, or -?**

  Command-Line Format
  
  **--help**

  Causes ndb_config to print a list of available options, and then exit.

• **--version, -V**

  Command-Line Format
  
  **--version**

  Causes ndb_config to print a version information string, and then exit.

• **--configinfo --xml**
Cause `ndb_config --configinfo` to provide output as XML by adding this option. A portion of such output is shown in this example:

```bash
$> ndb_config --configinfo --xml
<configvariables protocolversion="1" ndbversionstring="5.7.44-ndb-7.5.35"
    ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
    ndbversionbuild="0">
    <section name="SYSTEM">
        <param name="Name" comment="Name of system (NDB Cluster)"
            type="string" mandatory="true"/>
        <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
            type="unsigned" default="0" min="0" max="4294967039"/>
        <param name="ConfigGenerationNumber" comment="Configuration generation number"
            type="unsigned" default="0" min="0" max="4294967039"/>
    </section>
    <section name="MYSQLD" primarykeys="NodeId">
        <param name="wan" comment="Use WAN TCP setting as default" type="bool"
            default="false"/>
        <param name="HostName" comment="Name of computer for this node"
            type="string" default=""/>
        <param name="Id" comment="NodeId" type="unsigned" mandatory="true"
            min="1" max="255" deprecated="true"/>  
        <param name="NodeId" comment="Number identifying application node (mysqld(API))"
            type="unsigned" mandatory="true" min="1" max="255"/>
        <param name="ExecuteOnComputer" comment="HostName" type="string"
            deprecated="true"/>
        ...
    </section>
</configvariables>
```

**Note**

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```xml
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
    restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included
only if the restart type is *system* (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```xml
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed" type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Parameters that are required are indicated with `mandatory="true"`, as shown here:

```xml
<param name="NodeId" comment="Number identifying application node (mysqld(API))" type="unsigned" mandatory="true" min="1" max="255"/>
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an initial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

---

**Important**

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

---

**Examples**

1. To obtain the node ID and type of each node in the cluster:

```bash
$> ./ndb_config --query=nodeid,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndbd_mgmd
6:mysql
7:mysql
8:mysql
9:mysql
```

   In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:
3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory` and `DataDir` parameters:

```
$> ./ndb_config --type=ndbd --query=nodeid,host,datamemory,datadir -f ':' -r '
'  
1 : 198.51.100.193 : 83886080 : /usr/local/mysql/cluster-data  
2 : 198.51.100.112 : 83886080 : /usr/local/mysql/cluster-data  
3 : 198.51.100.176 : 83886080 : /usr/local/mysql/cluster-data  
4 : 198.51.100.119 : 83886080 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively, as well as the short option `-q` to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the `--host` option:

```
$> ./ndb_config --host=198.51.100.176 -f ':' -r '
' -q id,type  
3:ndbd 5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--nodeid` option.

### 25.5.8 ndb_delete_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

**Usage**

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

Options that can be used with `ndb_delete_all` are shown in the following table. Additional descriptions follow the table.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--character-sets-dir</code></td>
<td>Directory containing character sets.</td>
</tr>
<tr>
<td><code>--connect-retries</code></td>
<td>Number of times to retry connection before giving up.</td>
</tr>
<tr>
<td><code>--connect-retry-delay</code></td>
<td></td>
</tr>
</tbody>
</table>

#### Options

- **--character-sets-dir**
  
  **Command-Line Format**
  
  `--character-sets-dir=path`
  
  Directory containing character sets.

- **--connect-retries**
  
  **Command-Line Format**
  
  `--connect-retries=#`
  
  **Type** Integer
  
  **Default Value** 12
  
  **Minimum Value** 0
  
  **Maximum Value** 12
  
  Number of times to retry connection before giving up.

- **--connect-retry-delay**
### ndb_delete_all — Delete All Rows from an NDB Table

**Command-Line Format**
```
--connect-retry-delay=#
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

- **--connect-string**

**Command-Line Format**
```
--connect-string=connection_string
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as **--ndb-connectstring**.

- **--core-file**

**Command-Line Format**
```
--core-file
```

Write core file on error; used in debugging.

- **--database, -d**

**Command-Line Format**
```
--database=name
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>TEST_DB</td>
</tr>
</tbody>
</table>

Name of the database containing the table to delete from.

- **--defaults-extra-file**

**Command-Line Format**
```
--defaults-extra-file=path
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

- **--defaults-file**

**Command-Line Format**
```
--defaults-file=path
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read default options from given file only.

- **--defaults-group-suffix**

**Command-Line Format**
```
--defaults-group-suffix=string
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with concat(group, suffix).
• **--diskscan**

Command-Line Format

```
--diskscan
```

Run a disk scan.

• **--help**

Command-Line Format

```
--help
```

Display help text and exit.

• **--login-path**

Command-Line Format

```
--login-path=path
```

Type

String

Default Value

[none]

Read given path from login file.

• **--no-login-paths**

Command-Line Format

```
--no-login-paths
```

Skips reading options from the login path file.

• **--ndb-connectstring**

Command-Line Format

```
--ndb-connectstring=connection_string
```

Type

String

Default Value

[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: [nodeid=id;] [host=]hostname[:port]. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

• **--ndb-mgm-tls**

Command-Line Format

```
--ndb-mgm-tls=level
```

Type

Enumeration

Default Value

relaxed

Valid Values

relaxed, strict

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

• **--ndb-mgmd-host**

Command-Line Format

```
--ndb-mgmd-host=connection_string
```

Type

String

Default Value

[none]

Same as `--ndb-connectstring`.  

4110
ndb_delete_all — Delete All Rows from an NDB Table

• **--ndb-nodeid**

  Command-Line Format  
  --ndb-nodeid=#

  Type  
  Integer

  Default Value  
  [none]

  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

• **--ndb-optimized-node-selection**

  Command-Line Format  
  --ndb-optimized-node-selection

  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

• **--ndb-tls-search-path**

  Command-Line Format  
  --ndb-tls-search-path=list

  Type  
  Path name

  Default Value (Unix)  
  $HOME/ndb-tls

  Default Value (Windows)  
  $HOMEDIR/ndb-tls

  Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:) ; on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

  Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

  If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using **-DWITH_NDB_TLS_SEARCH_PATH**.

• **--no-defaults**

  Command-Line Format  
  --no-defaults

  Do not read default options from any option file other than login file.

• **--print-defaults**

  Command-Line Format  
  --print-defaults

  Print program argument list and exit.

• **--transactional, -t**

  Use of this option causes the delete operation to be performed as a single transaction.

  **Warning**

  With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

• **--tupscan**
Run a tuple scan.

• **--usage**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--usage</th>
</tr>
</thead>
</table>

Display help text and exit; same as **--help**.

• **--version**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--version</th>
</tr>
</thead>
</table>

Display version information and exit.

## 25.5.9 ndb_desc — Describe NDB Tables

**ndb_desc** provides a detailed description of one or more **NDB** tables.

### Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
```

```
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with **ndb_desc** are listed later in this section.

### Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (  
id INT NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT NOT NULL,
    weight_gm INT NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
    (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
    (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
    (NULL, 'grouper', 900, 125000), (NULL ,'puffer', 250, 2500);
```

Output from **ndb_desc**:

```
$> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80

</tbody>
</table>

Information about multiple tables can be obtained in a single invocation of ndb_desc by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the --table (short form: -t) option and supplying the name of the index as the first argument to ndb_desc, as shown here:

$> ./ndb_desc uk -d test -t fish
-- uk --
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 2

Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex

When an index is specified in this way, the --extra-partition-info and --extra-node-info options have no effect.

The Version column in the output contains the table's schema object version. For information about interpreting this value, see NDB Schema Object Versions.
Three of the table properties that can be set using \texttt{NDB\ TABLE} comments embedded in \texttt{CREATE\ TABLE} and \texttt{ALTER\ TABLE} statements are also visible in \texttt{ndb\ desc} output. The table's \texttt{FRAGMENT\ COUNT\ TYPE} is always shown in the \texttt{FragmentCountType} column. \texttt{READ\ ONLY} and \texttt{FULLY\ REPLIATED}, if set to 1, are shown in the \texttt{Table\ options} column. You can see this after executing the following \texttt{ALTER\ TABLE} statement in the \texttt{mysql} client:

```
mysql> ALTER TABLE fish COMMENT='NDB\ TABLE=READ\ ONLY=1,FULLY\ REPLIATED=1';
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS\G
+---------+------+---------------------------------------------------------------------------------------------------------+
| Level   | Code | Message                                                                                                 |
|---------+------|---------------------------------------------------------------------------------------------------------|
| Warning | 1296 | Got error 4503 'Table property is FRAGMENT_COUNT_TYPE=ONE_PER_LDM_PER_NODE but not in comment' from NDB |
+---------+------+---------------------------------------------------------------------------------------------------------+
1 row in set (0.00 sec)
```

The warning is issued because \texttt{READ\ ONLY=1} requires that the table's fragment count type is (or be set to) \texttt{ONE_PER_LDM_PER_NODE\ GROUP}; \texttt{NDB} sets this automatically in such cases. You can check that the \texttt{ALTER\ TABLE} statement has the desired effect using \texttt{SHOW\ CREATE\ TABLE}:

```
mysql> SHOW CREATE TABLE fish\G
*************************** 1. row ***************************
Table: fish
Create Table: CREATE TABLE `fish` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(20) NOT NULL,
  `length_mm` int(11) NOT NULL,
  `weight_gm` int(11) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `uk` (`name`) ) ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci COMMENT='NDB\ TABLE=READ\ BACKUP=1,FULLY\ REPLIATED=1'
1 row in set (0.01 sec)
```

Because \texttt{FRAGMENT\ COUNT\ TYPE} was not set explicitly, its value is not shown in the comment text printed by \texttt{SHOW\ CREATE\ TABLE}. \texttt{ndb\ desc}, however, displays the updated value for this attribute. The \texttt{Table\ options} column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```
$> ./ndb\ desc -c localhost fish -d test -p
-- fish --
Version: 4
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 380
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 1
FragmentCount: 1
FragmentCountType: ONE_PER_LDM_PER_NODE\ GROUP
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup, fullyreplicated
HashMap: DEFAULT-HASHMAP-3840-1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO\ INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY DYNAMIC
length_mm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
weight_gm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
```

4114
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex

-- Per partition info --

For more information about these table properties, see Section 15.1.20.12, “Setting NDB Comment Options”.

The Extent_space and Free extent_space columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

CREATE LOGFILE GROUP lg_1
   ADD UNDOFILE 'undo_1.log'
   INITIAL_SIZE 16M
   UNDO_BUFFER_SIZE 2M
   ENGINE NDB;

ALTER LOGFILE GROUP lg_1
   ADD UNDOFILE 'undo_2.log'
   INITIAL_SIZE 12M
   ENGINE NDB;

CREATE TABLESPACE ts_1
   ADD DATAFILE 'data_1.dat'
   USE LOGFILE GROUP lg_1
   INITIAL_SIZE 32M
   ENGINE NDB;

ALTER TABLESPACE ts_1
   ADD DATAFILE 'data_2.dat'
   INITIAL_SIZE 48M
   ENGINE NDB;

(For more information on the statements just shown and the objects created by them, see Section 25.6.11.1, “NDB Cluster Disk Data Objects”, as well as Section 15.1.16, “CREATE LOGFILE GROUP Statement”, and Section 15.1.21, “CREATE TABLESPACE Statement”.)

Now we can create and populate a version of the fish table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

DROP TABLE IF EXISTS fish;
CREATE TABLE fish
   (id INT NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT NOT NULL,
    weight_gm INT NOT NULL,
    PRIMARY KEY(pk (id)),
    UNIQUE KEY uk (name)) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;
INSERT INTO fish VALUES
   (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
   (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
   (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);

When run against this version of the table, ndb_desc displays the following output:

$> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1

4115
**Fragment type:** HashMapPartition

K Value: 6
Min load factor: 78
Max load factor: 80

TableStatus: Retrieved
Table options: readbackup
HashMap: DEFAULT-HASHMAP-3840-2
Tablespace id: 16
Tablespace: ts_1

--- Attributes ---

| Id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INC |
| name Varchar(80;utf8mb4_0900_ai_ci) NOT NULL AT=SHORT_VAR ST=MEMORY |
| length_mm Int NOT NULL AT=FIXED ST=DISK |
| weight_gm Int NOT NULL AT=FIXED ST=DISK |

--- Indexes ---

| PRIMARY KEY(id) - UniqueHashIndex |
| PRIMARY(id) - OrderedIndex |
| uk(name) - OrderedIndex |
| uk$unique(name) - UniqueHashIndex |

--- Per partition info ---

<table>
<thead>
<tr>
<th>Partition</th>
<th>Row count</th>
<th>Commit count</th>
<th>Frag fixed memory</th>
<th>Frag varsized memory</th>
<th>Extent_space</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>2</td>
<td>32768</td>
<td>32768</td>
<td>1048576</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>4</td>
<td>32768</td>
<td>32768</td>
<td>1048576</td>
</tr>
</tbody>
</table>

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the Information Schema `FILES` table.

**Tablespace id** and **Tablespace** are also displayed for Disk Data tables.

For fully replicated tables, `ndb_desc` shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. You can obtain such information, using the `mysql` client, from the `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables in the `ndbinfo` database.

All options that can be used with `ndb_desc` are shown in the following table. Additional descriptions follow the table.

- **--auto-inc, -a**
  Show the next value for a table's AUTO_INCREMENT column, if it has one.

- **--blob-info, -b**
  Include information about subordinate BLOB and TEXT columns.
  Use of this option also requires the use of the **--extra-partition-info (-p) option.**

- **--character-sets-dir**
Command-Line Format

--character-sets-dir=path

Directory containing character sets.

• **--connect-retries**

Command-Line Format

--connect-retries=#

Type: Integer
Default Value: 12
Minimum Value: 0
Maximum Value: 12

Number of times to retry connection before giving up.

• **--connect-retry-delay**

Command-Line Format

--connect-retry-delay=#

Type: Integer
Default Value: 5
Minimum Value: 0
Maximum Value: 5

Number of seconds to wait between attempts to contact management server.

• **--connect-string**

Command-Line Format

--connect-string=connection_string

Type: String
Default Value: [none]

Same as **--ndb-connectstring**.

• **--context, -x**

Show additional contextual information for the table such as schema, database name, table name, and the table's internal ID.

• **--core-file**

Command-Line Format

--core-file

Write core file on error; used in debugging.

• **--database=db_name, -d**

Specify the database in which the table should be found.

• **--defaults-extra-file**

Command-Line Format

--defaults-extra-file=path

Type: String
Default Value: [none]

Read given file after global files are read.

### ndb_mgm — Describe NDB Tables

- **--ndb-mgm-tls**

  **Command-Line Format**
  ```
  --ndb-mgm-tls=level
  ```

  **Type**
  Enumeration

  **Default Value**
  relaxed

  **Valid Values**
  relaxed, strict

  Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

- **--ndb-mgmd-host**

  **Command-Line Format**
  ```
  --ndb-mgmd-host=connection_string
  ```

  **Type**
  String

  **Default Value**
  [none]

  Same as **--ndb-connectstring**.

- **--ndb-nodeid**

  **Command-Line Format**
  ```
  --ndb-nodeid=#
  ```

  **Type**
  Integer

  **Default Value**
  [none]

  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--ndb-optimized-node-selection**

  **Command-Line Format**
  ```
  --ndb-optimized-node-selection
  ```

  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

- **--ndb-tls-search-path**

  **Command-Line Format**
  ```
  --ndb-tls-search-path=list
  ```

  **Type**
  Path name

  **Default Value (Unix)**
  $HOME/ndb-tls

  **Default Value (Windows)**
  $HOMEDIR/ndb-tls

  Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:) and on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute, and may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

  Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path is limited to the current working directory.

  If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using **-DWITH_NDB_TLS_SEARCH_PATH**.
ndb_drop_index — Drop Index from an NDB Table

- **--no-defaults**
  Command-Line Format: `--no-defaults`
  Do not read default options from any option file other than login file.

- **--print-defaults**
  Command-Line Format: `--print-defaults`
  Print program argument list and exit.

- **--retries=#, -r**
  Try to connect this many times before giving up. One connect attempt is made per second.

- **--table=tbl_name, -t**
  Specify the table in which to look for an index.

- **--unqualified, -u**
  Use unqualified table names.

- **--usage**
  Command-Line Format: `--usage`
  Display help text and exit; same as `--help`.

- **--version**
  Command-Line Format: `--version`
  Display version information and exit.

Table indexes listed in the output are ordered by ID.

**25.5.10 ndb_drop_index — Drop Index from an NDB Table**

ndb_drop_index drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

**Usage**

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

Options that can be used with `ndb_drop_index` are shown in the following table. Additional descriptions follow the table.

- **--character-sets-dir**
  Command-Line Format: `--character-sets-dir=path`
  Directory containing character sets.

- **--connect-retries**
  Command-Line Format: `--connect-retries=#`
**ndb_drop_index** — Drop Index from an NDB Table

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

Number of times to retry connection before giving up.

- **--connect-retry-delay**

  Command-Line Format    
  `--connect-retry-delay=#`

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

- **--connect-string**

  Command-Line Format    
  `--connect-string=connection_string`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as **--ndb-connectstring**.

- **--core-file**

  Command-Line Format    
  `--core-file`

Write core file on error; used in debugging.

- **--database, -d**

  Command-Line Format    
  `--database=name`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>TEST_DB</td>
</tr>
</tbody>
</table>

Name of the database in which the table resides.

- **--defaults-extra-file**

  Command-Line Format    
  `--defaults-extra-file=path`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

- **--defaults-file**

  Command-Line Format    
  `--defaults-file=path`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read default options from given file only.
### ndb_drop_index — Drop Index from an NDB Table

- **--defaults-group-suffix**

  Command-Line Format: `--defaults-group-suffix=string`
  
  **Type**: String
  
  **Default Value**: [none]

  Also read groups with `concat(group, suffix)`.

- **--help**

  Command-Line Format: `--help`

  Display help text and exit.

- **--login-path**

  Command-Line Format: `--login-path=path`

  **Type**: String

  **Default Value**: [none]

  Read given path from login file.

- **--no-login-paths**

  Command-Line Format: `--no-login-paths`

  Skips reading options from the login path file.

- **--ndb-connectstring**

  Command-Line Format: `--ndb-connectstring=connection_string`

  **Type**: String

  **Default Value**: [none]

- **--ndb-mgm-tls**

  Command-Line Format: `--ndb-mgm-tls=level`

  **Type**: Enumeration

  **Default Value**: relaxed

  **Valid Values**: relaxed, strict

  Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

- **--ndb-mgmd-host**

  Command-Line Format: `--ndb-mgmd-host=connection_string`

  **Type**: String
ndb_drop_index — Drop Index from an NDB Table

Default Value

[none]

Same as --ndb-connectstring.

• --ndb-nodeid

Command-Line Format

--ndb-nodeid=#

Type

Integer

Default Value

[none]

Set node ID for this node, overriding any ID set by --ndb-connectstring.

• --ndb-optimized-node-selection

Command-Line Format

--ndb-optimized-node-selection

Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

• --ndb-tls-search-path

Command-Line Format

--ndb-tls-search-path=list

Type

Path name

Default Value (Unix)

$HOME/ndb-tls

Default Value (Windows)

$HOMEDIR/ndb-tls

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using -DWITH_NDB_TLS_SEARCH_PATH.

• --no-defaults

Command-Line Format

--no-defaults

Do not read default options from any option file other than login file.

• --print-defaults

Command-Line Format

--print-defaults

Print program argument list and exit.

• --usage

Command-Line Format

--usage

Display help text and exit; same as --help.
Warning

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
$> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK
$> ./mysql -u jon -p ctest1
Enter password: *******
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.7.44-ndb-7.5.35
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SHOW TABLES;
+------------------+
| Tables_in_ctest1 |
+------------------+
| a                |
| bt1              |
| bt2              |
| dogs             |
| employees        |
| fish             |
+------------------+
6 rows in set (0.00 sec)
mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your only option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see Section 25.5.11, “ndb_drop_table — Drop an NDB Table”) to drop the table.

### 25.5.11 ndb_drop_table — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

#### Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

Options that can be used with `ndb_drop_table` are shown in the following table. Additional descriptions follow the table.

- **--character-sets-dir**

  Directory containing character sets.
ndb_drop_table — Drop an NDB Table

- **--connect-retries**
  
  Command-Line Format: `--connect-retries=#`
  
<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>
  
  Number of times to retry connection before giving up.

- **--connect-retry-delay**
  
  Command-Line Format: `--connect-retry-delay=#`
  
<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>
  
  Number of seconds to wait between attempts to contact management server.

- **--connect-string**
  
  Command-Line Format: `--connect-string=connection_string`
  
<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>
  
  Same as `--ndb-connectstring`.

- **--core-file**
  
  Command-Line Format: `--core-file`
  
  Write core file on error; used in debugging.

- **--database, -d**
  
  Command-Line Format: `--database=name`
  
<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>TEST_DB</td>
</tr>
</tbody>
</table>
  
  Name of the database in which the table resides.

- **--defaults-extra-file**
  
  Command-Line Format: `--defaults-extra-file=path`
  
<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>
  
  Read given file after global files are read.

- **--defaults-file**
  
  Command-Line Format: `--defaults-file=path`
  
<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>
ndb_drop_table — Drop an NDB Table

Default Value  [none]

Read default options from given file only.

• **--defaults-group-suffix**

  Command-Line Format  --defaults-group-suffix=string
  Type  String
  Default Value  [none]

  Also read groups with concat(group, suffix).

• **--help**

  Command-Line Format  --help

  Display help text and exit.

• **--login-path**

  Command-Line Format  --login-path=path
  Type  String
  Default Value  [none]

  Read given path from login file.

• **--no-login-paths**

  Command-Line Format  --no-login-paths

  Skips reading options from the login path file.

• **--ndb-connectstring**

  Command-Line Format  --ndb-connectstring=connection_string
  Type  String
  Default Value  [none]

  Set connection string for connecting to ndb_mgmd. Syntax: [nodeid=id;] [host=]hostname[:port]. Overrides entries in NDB_CONNECTSTRING and my.cnf.

• **--ndb-mgm-tls**

  Command-Line Format  --ndb-mgm-tls=level
  Type  Enumeration
  Default Value  relaxed
  Valid Values  relaxed  strict

  Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

• **--ndb-mgmd-host**

  4126
### ndb_drop_table — Drop an NDB Table

**Command-Line Format**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--ndb-mgmd-host=connection_string</td>
<td>Type: String; Default Value: [none] Same as --ndb-connectstring.</td>
</tr>
</tbody>
</table>

**Argument**

- **--ndb-nodeid**

  **Command-Line Format**
  
  `--ndb-nodeid=#`

  **Type** Integer
  
  **Default Value** [none]

  Set node ID for this node, overriding any ID set by --ndb-connectstring.

**Argument**

- **--ndb-optimized-node-selection**

  **Command-Line Format**
  
  `--ndb-optimized-node-selection`

  Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

**Argument**

- **--ndb-tls-search-path**

  **Command-Line Format**
  
  `--ndb-tls-search-path=list`

  **Type** Path name

  **Default Value (Unix)** $HOME/ndb-tls

  **Default Value (Windows)** $HOMEDIR/ndb-tls

  Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:) ; on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

  Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

  If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using -DWITH_NDB_TLS_SEARCH_PATH.

**Argument**

- **--no-defaults**

  **Command-Line Format**
  
  `--no-defaults`

  Do not read default options from any option file other than login file.

**Argument**

- **--print-defaults**

  **Command-Line Format**
  
  `--print-defaults`

  Print program argument list and exit.
ndb_error_reporter is a utility used to create an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.

Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDhhmmss.tar.bz2`, where `YYYYMMDDhhmmss` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- **--connection-timeout=timeout**

  ```
  Command-Line Format --connection-timeout=#
  Type Integer
  Default Value 0
  ```

  Wait this many seconds when trying to connect to nodes before timing out.

- **--dry-scp**

  ```
  Command-Line Format --dry-scp
  ```

  Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

- **--help**

  ```
  Command-Line Format --help
  ```

  Display help text and exit.

- **--fs**

  ```
  Command-Line Format --fs
  ```

  Copy the data node file systems to the management host and include them in the archive.
Because data node file systems can be extremely large, even after being compressed, we ask that you please do not send archives created using this option to Oracle unless you are specifically requested to do so.

- **--skip-nodegroup=nodegroup_id**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connection-timeout=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Skip all nodes belong to the node group having the supplied node group ID.

### 25.5.13 ndb_import — Import CSV Data Into NDB

`ndb_import` imports CSV-formatted data, such as that produced by `mysqldump --tab`, directly into NDB using the NDB API. `ndb_import` requires a connection to an NDB management server (`ndb_mgmd`) to function; it does not require a connection to a MySQL Server.

#### Usage

`ndb_import` requires two arguments. `db_name` is the name of the database where the table into which to import the data is found; `file_name` is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file’s extension, if any, is not taken into consideration. Options supported by `ndb_import` include those for specifying field separators, escapes, and line terminators, and are described later in this section.

`ndb_import` rejects any empty lines which it reads from the CSV file, except when importing a single column, in which case an empty value can be used as the column value. `ndb_import` handles this in the same manner as a `LOAD DATA` statement does.

`ndb_import` must be able to connect to an NDB Cluster management server; for this reason, there must be an unused [api] slot in the cluster `config.ini` file.

To duplicate an existing table that uses a different storage engine, such as InnoDB, as an NDB table, use the `mysql` client to perform a `SELECT INTO OUTFILE` statement to export the existing table to a CSV file, then to execute a `CREATE TABLE LIKE` statement to create a new table having the same structure as the existing table, then perform `ALTER TABLE ... ENGINE=NDB` on the new table; after this, from the system shell, invoke `ndb_import` to load the data into the new NDB table. For example, an existing InnoDB table named `myinnodb_table` in a database named `myinnodb` can be exported into an NDB table named `myndb_table` in a database named `myndb` as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the `mysql` client:

   ```
   mysql> USE myinnodb;
   mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv' 
   >   FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\'
   >   LINES TERMINATED BY '\n'
   >   FROM myinnodbtable;
   mysql> CREATE DATABASE myndb;
   mysql> USE myndb;
   mysql> CREATE TABLE myndb_table LIKE myinnodb.myinnodb_table;
   mysql> ALTER TABLE myndb_table ENGINE=NDB;
   ```
Once the target database and table have been created, a running `mysqld` is no longer required. You can stop it using `mysqladmin shutdown` or another method before proceeding, if you wish.

2. In the system shell:

```
# if you are not already in the MySQL bin directory:
$> cd path-to-mysql-bin-dir

$> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by='"' \ 
   --fields-terminated-by="" --fields-escaped-by='\\'
```

The output should resemble what is shown here:

```
job-1 import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
$>
```

All options that can be used with `ndb_import` are shown in the following table. Additional descriptions follow the table.

- **--abort-on-error**
  
  **Command-Line Format**
  
  `--abort-on-error`

  Dump core on any fatal error; used for debugging only.

- **--ai-increment=###
  
  **Command-Line Format**
  
  `--ai-increment=#`

  **Type**
  
  Integer

  **Default Value**
  
  1

  **Minimum Value**
  
  1

  **Maximum Value**
  
  4294967295

  For a table with a hidden primary key, specify the autoincrement increment, like the `auto_increment_increment` system variable does in the MySQL Server.

- **--ai-offset=###
  
  **Command-Line Format**
  
  `--ai-offset=#`

  **Type**
  
  Integer

  **Default Value**
  
  1

  **Minimum Value**
  
  1

  **Maximum Value**
  
  4294967295

  For a table with hidden primary key, specify the autoincrement offset. Similar to the `auto_increment_offset` system variable.

- **--ai-prefetch-sz=#
  
  **Command-Line Format**
  
  `--ai-prefetch-sz=#`

  **Type**
  
  Integer
For a table with a hidden primary key, specify the number of autoincrement values that are prefetched. Behaves like the `ndb_autoincrement_prefetch_sz` system variable does in the MySQL Server.

- **--character-sets-dir**
  
  **Command-Line Format**
  
  `--character-sets-dir=path`
  
  Directory containing character sets.

- **--connections=**
  
  **Command-Line Format**
  
  `--connections=#`
  
  **Type**
  
  Integer
  
  **Default Value**
  
  1
  
  **Minimum Value**
  
  1
  
  **Maximum Value**
  
  4294967295
  
  Number of cluster connections to create.

- **--connect-retries**
  
  **Command-Line Format**
  
  `--connect-retries=#`
  
  **Type**
  
  Integer
  
  **Default Value**
  
  12
  
  **Minimum Value**
  
  0
  
  **Maximum Value**
  
  12
  
  Number of times to retry connection before giving up.

- **--connect-retry-delay**
  
  **Command-Line Format**
  
  `--connect-retry-delay=#`
  
  **Type**
  
  Integer
  
  **Default Value**
  
  5
  
  **Minimum Value**
  
  0
  
  **Maximum Value**
  
  5
  
  Number of seconds to wait between attempts to contact management server.

- **--connect-string**
  
  **Command-Line Format**
  
  `--connect-string=connection_string`
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Same as `--ndb-connectstring`.

- **--continue**
When a job fails, continue to the next job.

- **--continue**

Write core file on error; used in debugging.

- **--core-file**

Provides a shortcut method for setting typical CSV import options. The argument to this option is a string consisting of one or more of the following parameters:

  - **c**: Fields terminated by comma
  - **d**: Use defaults, except where overridden by another parameter
  - **n**: Lines terminated by \n
  - **q**: Fields optionally enclosed by double quote characters ("")
  - **r**: Line terminated by \r

The order of parameters used in the argument to this option is handled such that the rightmost parameter always takes precedence over any potentially conflicting parameters which have already been used in the same argument value. This also applies to any duplicate instances of a given parameter.

This option is intended for use in testing under conditions in which it is difficult to transmit escapes or quotation marks.

- **--db-workers=#**

Number of threads, per data node, executing database operations.

- **--defaults-file**

Read default options from given file only.

- **--defaults-extra-file**
ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-extra-file=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

- **--defaults-group-suffix**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-group-suffix=string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with concat(group, suffix).

- **--errins-type=name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--errins-type=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Valid Values</td>
<td>stopjob</td>
</tr>
<tr>
<td></td>
<td>stopall</td>
</tr>
<tr>
<td></td>
<td>sighup</td>
</tr>
<tr>
<td></td>
<td>sigint</td>
</tr>
<tr>
<td></td>
<td>list</td>
</tr>
</tbody>
</table>

Error insert type; use list as the name value to obtain all possible values. This option is used for testing purposes only.

- **--errins-delay=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--errins-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>ms</td>
</tr>
</tbody>
</table>

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

- **--fields-enclosed-by=char**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-enclosed-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

This works in the same way as the FIELDS ENCLOSED BY option does for the LOAD DATA statement, specifying a character to be interpreted as quoting field values. For CSV input, this is the same as --fields-optionally-enclosed-by.
- **--fields-escaped-by=name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-escaped-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\</td>
</tr>
</tbody>
</table>

  Specify an escape character in the same way as the FIELDS ESCAPED BY option does for the SQL LOAD DATA statement.

- **--fields-optionally-enclosed-by=char**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-optionally-enclosed-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

  This works in the same way as the FIELDS OPTIONALLY ENCLOSED BY option does for the LOAD DATA statement, specifying a character to be interpreted as optionally quoting field values. For CSV input, this is the same as --fields-enclosed-by.

- **--fields-terminated-by=char**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-terminated-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\t</td>
</tr>
</tbody>
</table>

  This works in the same way as the FIELDS TERMINATED BY option does for the LOAD DATA statement, specifying a character to be interpreted as the field separator.

- **--help**

  Command-Line Format --help

  Display help text and exit.

- **--idlesleep=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--idlesleep=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>ms</td>
</tr>
</tbody>
</table>

  Number of milliseconds to sleep waiting for more work to perform.

- **--idlespin=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--idlespin=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
ndb_import — Import CSV Data Into NDB

Number of times to retry before sleeping.

• **--ignore-lines=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ignore-lines=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Cause ndb_import to ignore the first # lines of the input file. This can be employed to skip a file header that does not contain any data.

• **--input-type=name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--input-type=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>csv</td>
</tr>
<tr>
<td>Valid Values</td>
<td>random</td>
</tr>
<tr>
<td></td>
<td>csv</td>
</tr>
</tbody>
</table>

Set the type of input type. The default is csv; random is intended for testing purposes only.

• **--input-workers=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--input-workers=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the number of threads processing input.

• **--keep-state**

By default, ndb_import removes all state files (except non-empty *.rej files) when it completes a job. Specify this option (nor argument is required) to force the program to retain all state files instead.

• **--lines-terminated-by=char**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lines-terminated-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\n</td>
</tr>
</tbody>
</table>

This works in the same way as the LINES TERMINATED BY option does for the LOAD DATA statement, specifying a character to be interpreted as end-of-line.
### ndb_import — Import CSV Data Into NDB

- **--log-level=#**

  **Command-Line Format**: `--log-level=#`
  **Type**: Integer
  **Default Value**: 0
  **Minimum Value**: 0
  **Maximum Value**: 2

  Performs internal logging at the given level. This option is intended primarily for internal and development use.

  In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

- **--login-path**

  **Command-Line Format**: `--login-path=path`
  **Type**: String
  **Default Value**: [none]

  Read given path from login file.

- **--no-login-paths**

  **Command-Line Format**: `--no-login-paths`

  Skips reading options from the login path file.

- **--max-rows=#**

  **Command-Line Format**: `--max-rows=#`
  **Type**: Integer
  **Default Value**: 0
  **Minimum Value**: 0
  **Maximum Value**: 4294967295
  **Unit**: bytes

  Import only this number of input data rows; the default is 0, which imports all rows.

- **--missing-ai-column**

  **Command-Line Format**: `--missing-ai-column='name'`
  **Type**: Boolean
  **Default Value**: FALSE

  This option can be employed when importing a single table, or multiple tables. When used, it indicates that the CSV file being imported does not contain any values for an AUTO_INCREMENT column, and that ndb_import should supply them; if the option is used and the AUTO_INCREMENT column contains any values, the import operation cannot proceed.

- **--monitor=#**

  **Command-Line Format**: `--monitor=#`
  **Type**: Integer
### ndb_import — Import CSV Data Into NDB

| Default Value | 2 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |
| Unit          | bytes |

Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- **--ndb-connectstring**

  **Command-Line Format**
  
  ```bash
  --ndb-connectstring=connection_string
  ```

  **Type**
  
  String

  **Default Value**
  
  [none]

- **--ndb-mgm-tls**

  **Command-Line Format**
  
  ```bash
  --ndb-mgm-tls=level
  ```

  **Type**
  
  Enumeration

  **Default Value**
  
  relaxed

  **Valid Values**
  
  relaxed, strict

  Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- **--ndb-mgmd-host**

  **Command-Line Format**
  
  ```bash
  --ndb-mgmd-host=connection_string
  ```

  **Type**
  
  String

  **Default Value**
  
  [none]

  Same as `--ndb-connectstring`.

- **--ndb-nodeid**

  **Command-Line Format**
  
  ```bash
  --ndb-nodeid=#
  ```

  **Type**
  
  Integer

  **Default Value**
  
  [none]

  Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- **--ndb-optimized-node-selection**

  **Command-Line Format**
  
  ```bash
  --ndb-optimized-node-selection
  ```

  Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.
• **--ndb-tls-search-path**

Command-Line Format  
--ndb-tls-search-path=list

<table>
<thead>
<tr>
<th>Type</th>
<th>Path name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value (Unix)</td>
<td>$HOME/ndb-tls</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td>$HOMEDIR/ndb-tls</td>
</tr>
</tbody>
</table>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `DWITH_NDB_TLS_SEARCH_PATH`.

• **--no-asynch**

Command-Line Format  
--no-asynch

Run database operations as batches, in single transactions.

• **--no-defaults**

Command-Line Format  
--no-defaults

Do not read default options from any option file other than login file.

• **--no-hint**

Command-Line Format  
--no-hint

Do not use distribution key hinting to select a data node.

• **--opbatch=#**

Command-Line Format  
--opbatch=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.

• **--opbytes=#**

Command-Line Format  
--opbytes=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
</table>
ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Default Value</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Set a limit on the number of bytes per execution batch. Use 0 for no limit.

- **--output-type**=

  **Command-Line Format**
  
  --output-type=name

  **Type**
  
  Enumeration

  **Default Value**
  
  ndb

  **Valid Values**
  
  null

  Set the output type. ndb is the default. null is used only for testing.

- **--output-workers**=

  **Command-Line Format**
  
  --output-workers=#

  **Type**
  
  Integer

  **Default Value**
  
  2

  **Minimum Value**
  
  1

  **Maximum Value**
  
  4294967295

  Set the number of threads processing output or relaying database operations.

- **--pagesize**=

  **Command-Line Format**
  
  --pagesize=#

  **Type**
  
  Integer

  **Default Value**
  
  4096

  **Minimum Value**
  
  1

  **Maximum Value**
  
  4294967295

  **Unit**
  
  bytes

  Align I/O buffers to the given size.

- **--pagecnt**=

  **Command-Line Format**
  
  --pagecnt=#

  **Type**
  
  Integer

  **Default Value**
  
  64

  **Minimum Value**
  
  1

  **Maximum Value**
  
  4294967295

  Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- **--polltimeout**=

  **Command-Line Format**
  
  --polltimeout=#
ndb_import — Import CSV Data Into NDB

- **--print-defaults**

  **Command-Line Format**
  ```plaintext
  --print-defaults
  ```

  Print program argument list and exit.

- **--rejects=#**

  **Command-Line Format**
  ```plaintext
  --rejects=#
  ```

  Type: Integer  
  Default Value: 0  
  Minimum Value: 0  
  Maximum Value: 4294967295  

  Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the .rej file.

  The limit imposed by this option is effective for the duration of the current run. A run restarted using **--resume** is considered a “new” run for this purpose.

- **--resume**

  **Command-Line Format**
  ```plaintext
  --resume
  ```

  If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

- **--rowbatch=#**

  **Command-Line Format**
  ```plaintext
  --rowbatch=#
  ```

  Type: Integer  
  Default Value: 0  
  Minimum Value: 0  
  Maximum Value: 4294967295  
  Unit: rows

  Set a limit on the number of rows per row queue. Use 0 for no limit.

- **--rowbytes=#**

  **Command-Line Format**
  ```plaintext
  --rowbytes=#
  ```

  Type: Integer  
  Default Value: 262144  
  Unit: bytes

Set a timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or until an error occurs.
Minimum Value
0
Maximum Value
4294967295
Unit
bytes

Set a limit on the number of bytes per row queue. Use 0 for no limit.

- **--stats**

Command-Line Format
```
--stats
```

Save information about options related to performance and other internal statistics in files named
*.sto and *.stt. These files are always kept on successful completion (even if --keep-state is
not also specified).

- **--state-dir=**

Command-Line Format
```
--state-dir=path
```

Type
String
Default Value
.

Where to write the state files (tbl_name.map, tbl_name.rej, tbl_name.res, and
tbl_name.stt) produced by a run of the program; the default is the current directory.

- **--table=**

Command-Line Format
```
--table=name
```

Type
String
Default Value
[input file base name]

By default, ndb_import attempts to import data into a table whose name is the base name of the
CSV file from which the data is being read. You can override the choice of table name by specifying
it with the **--table** option (short form **-t**).

- **--tempdelay=#**

Command-Line Format
```
--tempdelay=#
```

Type
Integer
Default Value
10
Minimum Value
0
Maximum Value
4294967295
Unit
ms

Number of milliseconds to sleep between temporary errors.

- **--temperrors=#**

Command-Line Format
```
--temperrors=#
```

Type
Integer
Default Value
0
Minimum Value
0
Maximum Value | 4294967295
---|---
Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the .rej file.

- **--verbose, -v**
  
  **Command-Line Format**: `--verbose[=#]`
  
  **Type**: Boolean
  
  **Default Value**: `false`

  Enable verbose output.

- **--usage**
  
  **Command-Line Format**: `--usage`
  
  Display help text and exit; same as `--help`.

- **--version**
  
  **Command-Line Format**: `--version`
  
  Display version information and exit.

As with `LOAD DATA`, options for field and line formatting much match those used to create the CSV file, whether this was done using `SELECT INTO ... OUTFILE`, or by some other means. There is no equivalent to the `LOAD DATA` statement `STARTING WITH` option.

**25.5.14 ndb_index_stat — NDB Index Statistics Utility**

`ndb_index_stat` provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

**Usage**

To obtain basic index statistics about a given NDB table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database (-d)` option:

```
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an NDB table named `mytable` in the `test` database:

```
$> ndb_index_stat -d test mytable
```

`sampleVersion` is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes `sampleVersion` to be incremented.

`loadTime` shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

`sampleCount` is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).
sampleCount can be compared with the cardinality of `SHOW INDEX` or `INFORMATION_SCHEMA.STATISTICS`, although the latter two provide a view of the table as a whole, while `ndb_index_stat` provides a per-fragment average.

keyBytes is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so keyBytes can be calculated in this case as shown here:

\[
\text{keyBytes} = \text{sampleCount} \times (4 \text{ bytes per index}) = 1994 \times 4 = 7976
\]

This information can also be obtained using the corresponding column definitions from `INFORMATION_SCHEMA.COLUMNS` (this requires a MySQL Server and a MySQL client application).

totalBytes is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of `ndb_index_stat`.

The `--verbose` option provides some additional output, as shown here:

```
$> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected
```

If the output from the program is empty, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke `ndb_index_stat` with the `--update` option, or execute `ANALYZE TABLE` on the table in the `mysql` client.

**Options**

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table.

- **--character-sets-dir**

  **Command-Line Format**

  `--character-sets-dir=path`

  Directory containing character sets.

- **--connect-retries**

  **Command-Line Format**

  `--connect-retries=#`

  **Type**
  Integer

  **Default Value**
  12

  **Minimum Value**
  0

  **Maximum Value**
  12

  Number of times to retry connection before giving up.

- **--connect-retry-delay**

  **Command-Line Format**

  `--connect-retry-delay=#`
**ndb_index_stat — NDB Index Statistics Utility**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>5</td>
<td>0</td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

- **--connect-string**
  
  **Command-Line Format** — `--connect-string=connection_string`
  
  **Type** — String
  
  **Default Value** — [none]

  Same as **--ndb-connectstring**.

- **--core-file**
  
  **Command-Line Format** — `--core-file`

  Write core file on error; used in debugging.

- **--database=name, -d name**
  
  **Command-Line Format** — `--database=name`
  
  **Type** — String
  
  **Default Value** — [none]

  The name of the database that contains the table being queried.

- **--defaults-extra-file**
  
  **Command-Line Format** — `--defaults-extra-file=path`
  
  **Type** — String
  
  **Default Value** — [none]

  Read given file after global files are read.

- **--defaults-file**
  
  **Command-Line Format** — `--defaults-file=path`
  
  **Type** — String
  
  **Default Value** — [none]

  Read default options from given file only.

- **--defaults-group-suffix**
  
  **Command-Line Format** — `--defaults-group-suffix=string`
  
  **Type** — String
  
  **Default Value** — [none]

  Also read groups with concat(group, suffix).
• **--delete**

Command-Line Format: `--delete`

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

• **--dump**

Command-Line Format: `--dump`

Dump the contents of the query cache.

• **--help**

Command-Line Format: `--help`

Display help text and exit.

• **--login-path**

Command-Line Format: `--login-path=path`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given path from login file.

• **--no-login-paths**

Command-Line Format: `--no-login-paths`

Skips reading options from the login path file.

• **--loops=**

Command-Line Format: `--loops=#`

<table>
<thead>
<tr>
<th>Type</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

Repeat commands this number of times (for use in testing).

• **--ndb-connectstring**

Command-Line Format: `--ndb-connectstring=connection_string`

• **--ndb-mgm-tls**

Command-Line Format: `--ndb-mgm-tls=level`
### ndb_index_stat — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Type</th>
<th>Enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>relaxed</td>
</tr>
<tr>
<td>Valid Values</td>
<td>relaxed, strict</td>
</tr>
</tbody>
</table>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- **--ndb-mgmd-host**

  **Command-Line Format**

  `--ndb-mgmd-host=connection_string`

  **Type**

  String

  **Default Value**

  [none]

  Same as **--ndb-connectstring**.

- **--ndb-nodeid**

  **Command-Line Format**

  `--ndb-nodeid=#`

  **Type**

  Integer

  **Default Value**

  [none]

  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--ndb-optimized-node-selection**

  **Command-Line Format**

  `--ndb-optimized-node-selection`

  Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- **--ndb-tls-search-path**

  **Command-Line Format**

  `--ndb-tls-search-path=list`

  **Type**

  Path name

  **Default Value (Unix)**

  `$HOME/ndb-tls`

  **Default Value (Windows)**

  `$HOMEDIR/ndb-tls`

  Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (`:`); on Windows systems, the semicolon character (`;`) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (`$`), and expanded prior to use.

  Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (`.`) indicates that the search path limited to the current working directory.

  If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `DWITH_NDB_TLS_SEARCH_PATH`. 

---

4146
--no-defaults
Command-Line Format --no-defaults
Do not read default options from any option file other than login file.

--print-defaults
Command-Line Format --print-defaults
Print program argument list and exit.

--query=
Command-Line Format --query=#
Type Numeric
Default Value 0
Minimum Value 0
Maximum Value MAX_INT
Perform random range queries on first key attribute (must be int unsigned).

--sys-drop
Command-Line Format --sys-drop
Drop all statistics tables and events in the NDB kernel. This causes all statistics to be lost.

--sys-create
Command-Line Format --sys-create
Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

--sys-create-if-not-exist
Command-Line Format --sys-create-if-not-exist
Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

--sys-create-if-not-valid
Command-Line Format --sys-create-if-not-valid
Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

--sys-check
Command-Line Format --sys-check
Verify that all required system statistics tables and events exist in the NDB kernel.

--sys-skip-tables
Command-Line Format --sys-skip-tables
Do not apply any --sys-* options to any statistics tables.

- **--sys-skip-events**
  
  Command-Line Format  
  
  --sys-skip-events

Do not apply any --sys-* options to any events.

- **--update**
  
  Command-Line Format  
  
  --update

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- **--usage**
  
  Command-Line Format  
  
  --usage

Display help text and exit; same as --help.

- **--verbose**
  
  Command-Line Format  
  
  --verbose

Turn on verbose output.

- **--version**
  
  Command-Line Format  
  
  --version

Display version information and exit.

**ndb_index_stat system options.**  The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see **ndb_index_stat statistics options**).

- **--sys-drop**
- **--sys-create**
- **--sys-create-if-not-exist**
- **--sys-create-if-not-valid**
- **--sys-check**
- **--sys-skip-tables**
- **--sys-skip-events**

**ndb_index_stat statistics options.**  The options listed here are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see **ndb_index_stat system options**).

- **--database**
- **--delete**
- **--update**
ndb_move_data — NDB Data Copy Utility

- --dump
- --query

25.5.15 ndb_move_data — NDB Data Copy Utility

ndb_move_data copies data from one NDB table to another.

Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

Options that can be used with ndb_move_data are shown in the following table. Additional descriptions follow the table.

- --abort-on-error
  
  Command-Line Format
  
  ```
  --abort-on-error
  ```
  
  Dump core on permanent error (debug option).

- --character-sets-dir=dir_name
  
  Command-Line Format
  
  ```
  --character-sets-dir=path
  ```
  
  Directory where character sets are.

- --connect-retry-delay
  
  Command-Line Format
  
  ```
  --connect-retry-delay=
  ```
  
  Type Integer
  Default Value 5
  Minimum Value 0
  Maximum Value 5

  Number of seconds to wait between attempts to contact management server.

- --connect-retries
  
  Command-Line Format
  
  ```
  --connect-retries=
  ```
  
  Type Integer
  Default Value 12
  Minimum Value 0
  Maximum Value 12

  Number of times to retry connection before giving up.

- --connect-string
  
  Command-Line Format
  
  ```
  --connect-string=connection_string
  ```

4150
## Command-Line Format

**--exclude-missing-columns**

Ignore extra columns in source or target table.

**--help**

Display help text and exit.

**--login-path**

Read given path from login file.

**--no-login-paths**

Skips reading options from the login path file.

**--lossy-conversions, -l**

Allow attribute data to be truncated when converted to a smaller type.

**--ndb-connectstring**

Set connection string for connecting to ndb_mgmd. Syntax: 
[nodeid=]id;
[host=]hostname[:port]. Overrides entries in NDB_CONNECTSTRING and my.cnf.

**--ndb-mgm-tls**

Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

**--ndb-mgmd-host**
### ndb_move_data — NDB Data Copy Utility

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as **--ndb-connectstring**.

- **--ndb-nodeid**

  **Command-Line Format**
  
  --ndb-nodeid=#

  **Type**
  
  Integer

  **Default Value**
  
  [none]

  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--ndb-optimized-node-selection**

  **Command-Line Format**
  
  --ndb-optimized-node-selection

  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

- **--ndb-tls-search-path**

  **Command-Line Format**
  
  --ndb-tls-search-path=list

  **Type**
  
  Path name

  **Default Value (Unix)**
  
  $HOME/ndb-tls

  **Default Value (Windows)**
  
  $HOMEDIR/ndb-tls

  Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

  Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path is limited to the current working directory.

  If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `.\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using **--DWITH_NDB_TLS_SEARCH_PATH**.

- **--no-defaults**

  **Command-Line Format**
  
  --no-defaults

  Do not read default options from any option file other than login file.

- **--print-defaults**

  **Command-Line Format**
  
  --print-defaults

  Print program argument list and exit.
ndb_perror — Obtain NDB Error Message Information

- **--promote-attributes, -A**
  
  Command-Line Format: `--promote-attributes`

  Allow attribute data to be converted to a larger type.

- **--staging-tries=x[,y[,z]]**
  
  Command-Line Format: `--staging-tries=x[,y[,z]]`

  Type: String
  Default Value: `0,1000,60000`

  Specify tries on temporary errors. Format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

- **--usage**
  
  Command-Line Format: `--usage`

  Display help text and exit; same as `--help`.

- **--verbose**
  
  Command-Line Format: `--verbose`

  Enable verbose messages.

- **--version**
  
  Command-Line Format: `--version`

  Display version information and exit.

### 25.5.16 ndb_perror — Obtain NDB Error Message Information

`ndb_perror` shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. This is intended as a drop-in replacement for `perror --ndb`, which is no longer supported.

**Usage**

```
ndb_perror [options] error_code
```

`ndb_perror` does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```
$> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

To display only the error message, invoke `ndb_perror` with the `--silent` option (short form `-s`), as shown here:

```
$> ndb_perror -s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like `perror`, `ndb_perror` accepts multiple error codes:

```
$> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
```

4153
NDB error code 1001: Illegal connect string

Additional program options for `ndb_perror` are described later in this section.

`ndb_perror` replaces `perror --ndb`, which is no longer supported by NDB Cluster. To make substitution easier in scripts and other applications that might depend on `perror` for obtaining NDB error information, `ndb_perror` supports its own “dummy” `--ndb` option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program `ndb_perror`. Additional descriptions follow the table.

### Additional Options

- **--defaults-extra-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--defaults-extra-file=path</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
  Type: String
  Default Value: [none]

  Read given file after global files are read.

- **--defaults-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--defaults-file=path</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
  Type: String
  Default Value: [none]

  Read default options from given file only.

- **--defaults-group-suffix**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--defaults-group-suffix=string</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
  Type: String
  Default Value: [none]

  Also read groups with concat(group, suffix).

- **--help, --?**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--help</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
  Display program help text and exit.

- **--login-path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--login-path=path</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
  Type: String
  Default Value: [none]

  Read given path from login file.

- **--no-login-paths**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--no-login-paths</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
  Skips reading options from the login path file.
ndb_print_backup_file — Print NDB Backup File Contents

- **--ndb**

  Command-Line Format: **--ndb**

  For compatibility with applications depending on old versions of **perror** that use that program's **--ndb** option. The option when used with **ndb_perror** does nothing, and is ignored by it.

- **--no-defaults**

  Command-Line Format: **--no-defaults**

  Do not read default options from any option file other than login file.

- **--print-defaults**

  Command-Line Format: **--print-defaults**

  Print program argument list and exit.

- **--silent, -s**

  Command-Line Format: **--silent**

  Show error message only.

- **--version, -V**

  Command-Line Format: **--version**

  Print program version information and exit.

- **--verbose, -v**

  Command-Line Format: **--verbose**

  Verbose output; disable with **--silent**.

25.5.17 ndb_print_backup_file — Print NDB Backup File Contents

ndb_print_backup_file obtains diagnostic information from a cluster backup file.

**Usage**

```
ndb_print_backup_file [-P password] file_name
```

*file_name* is the name of a cluster backup file. This can be any of the files (*Data*, *.ctl*, or *.log* file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 25.6.8.1, “NDB Cluster Backup Concepts”.

Like **ndb_print_schema_file** and **ndb_print_sys_file** (and unlike most of the other **NDB** utilities that are intended to be run on a management server host or to connect to a management server) **ndb_print_backup_file** must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

This program can also be used to read undo log files.
**Options**

`ndb_print_backup_file` supports the options described in the following list.

- **--backup-key, -K**
  
  **Command-Line Format**  
  `--backup-key=key`
  
  Specify the key needed to decrypt an encrypted backup.

- **--backup-key-from-stdin**
  
  **Command-Line Format**  
  `--backup-key-from-stdin`
  
  Allow input of the decryption key from standard input, similar to entering a password after invoking `mysql --password` with no password supplied.

- **--backup-password**
  
  **Command-Line Format**  
  `--backup-password=password`
  
  **Type**  
  String
  
  **Default Value**  
  `[none]`
  
  Specify the password needed to decrypt an encrypted backup.

- **--backup-password-from-stdin**
  
  **Command-Line Format**  
  `--backup-password-from-stdin`
  
  Allow input of the password from standard input, similar to entering a password after invoking `mysql --password` with no password supplied.

- **--control-directory-number**
  
  **Command-Line Format**  
  `--control-directory-number=#`
  
  **Type**  
  Integer
  
  **Default Value**  
  `0`
  
  Control file directory number. Used together with **--print-restored-rows**.

- **--defaults-extra-file**
  
  **Command-Line Format**  
  `--defaults-extra-file=path`
  
  **Type**  
  String
  
  **Default Value**  
  `[none]`
  
  Read given file after global files are read.

- **--defaults-file**
  
  **Command-Line Format**  
  `--defaults-file=path`
  
  **Type**  
  String
  
  **Default Value**  
  `[none]`
  
  Read default options from given file only.

- **--defaults-group-suffix**
### ndb_print_backup_file — Print NDB Backup File Contents

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-group-suffix=string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with concat(group, suffix).

- **--fragment-id**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fragment-id=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Fragment ID. Used together with **--print-restored-rows**.

- **--help**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--help</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>--usage</td>
</tr>
</tbody>
</table>

Print program usage information.

- **--login-path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--login-path=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given path from login file.

- **--no-login-paths**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--no-login-paths</th>
</tr>
</thead>
</table>

Skips reading options from the login path file.

- **--no-defaults**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--no-defaults</th>
</tr>
</thead>
</table>

Do not read default options from any option file other than login file.

- **--no-print-rows**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--no-print-rows</th>
</tr>
</thead>
</table>

Do not include rows in output.

- **--print-defaults**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--print-defaults</th>
</tr>
</thead>
</table>

Print program argument list and exit.

- **--print-header-words**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--print-header-words</th>
</tr>
</thead>
</table>

|
Include header words in output.

- **--print-restored-rows**

  Command-Line Format  
  
  ```
  --print-restored-rows
  ```

  Include restored rows in output, using the file `LCP/c/TtFf.ctl`, for which the values are set as follows:
  
  - `c` is the control file number set using `--control-directory-number`
  - `t` is the table ID set using `--table-id`
  - `f` is the fragment ID set using `--fragment-id`

- **--print-rows**

  Command-Line Format  
  
  ```
  --print-rows
  ```

  Print rows. This option is enabled by default; to disable it, use `--no-print-rows`.

- **--print-rows-per-page**

  Command-Line Format  
  
  ```
  --print-rows-per-page
  ```

  Print rows per page.

- **--rowid-file**

  Command-Line Format  
  
  ```
  --rowid-file=path
  ```

  Type  
  File name

  Default Value  
  [none]

  File to check for row ID.

- **--show-ignored-rows**

  Command-Line Format  
  
  ```
  --show-ignored-rows
  ```

  Show ignored rows.

- **--table-id**

  Command-Line Format  
  
  ```
  --table-id=#
  ```

  Type  
  Integer

  Default Value  
  [none]

  Table ID. Used together with `--print-restored-rows`.

- **--usage**

  Command-Line Format  
  
  ```
  --usage
  ```

  Display help text and exit; same as `--help`.

- **--verbose**

  Command-Line Format  
  
  ```
  --verbose[=#]
  ```
**ndb_print_file** — Print NDB Disk Data File Contents

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Verbosity level of output. A greater value indicates increased verbosity.

- **--version**

Command-Line Format

```
--version
```

Display version information and exit.

### 25.5.18 ndb_print_file — Print NDB Disk Data File Contents

**ndb_print_file** obtains information from an NDB Cluster Disk Data file.

#### Usage

```
ndb_print_file [-v] [-q] file_name+
```

*file_name* is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like **ndb_print_schema_file** and **ndb_print_sys_file** (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) **ndb_print_file** must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

#### Options

**ndb_print_file** supports the following options:

- **--file-key, -K**

  Command-Line Format

  ```
  --file-key=hex_data
  ```

  Supply file system encryption or decryption key from stdin, tty, or a *my.cnf* file.

- **--file-key-from-stdin**

  Command-Line Format

  ```
  --file-key-from-stdin
  ```

  Type

<table>
<thead>
<tr>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
</tr>
<tr>
<td>Valid Values</td>
</tr>
</tbody>
</table>

  Supply file system encryption or decryption key from stdin.

- **--help, -h, -?**

  Command-Line Format

  ```
  --help
  ```

  Print help message and exit.

- **--quiet, -q**

  Command-Line Format

  ```
  --quiet
  ```
ndb_print_frag_file — Print NDB Fragment List File Contents

Suppress output (quiet mode).

- **--usage, -?**

  Command-Line Format
  ```
  --usage
  ```

  Print help message and exit.

- **--verbose, -v**

  Command-Line Format
  ```
  --verbose
  ```

  Make output verbose.

- **--version, -v**

  Command-Line Format
  ```
  --version
  ```

  Print version information and exit.

For more information, see Section 25.6.11, "NDB Cluster Disk Data Tables".

### 25.5.19 ndb_print_frag_file — Print NDB Fragment List File Contents

ndb_print_frag_file obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

**Usage**

```
ndb_print_frag_file file_name
```

`file_name` is the name of a cluster fragment list file, which matches the pattern `SX.FragList`, where `X` is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID `nodeid`, in directories named `ndb_nodeid_fs/DN/DBDIH/`, where `N` is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see NDB Cluster Data Node File System Directory.

Like `ndb_print_backup_file`, `ndb_print_sys_file`, and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), `ndb_print_frag_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

**Sample Output**

```
$> ndb_print_frag_file /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
noOfPages = 1 noOfWords = 182
Table Data
--------
Num Frags: 2 NoOfReplicas: 2 hashpointer: 4294967040
kvalue: 6 mask: 0x00000000 method: HashMap
Storage is on Logged and checkpointed, survives SR
------ Fragment with FragId: 0 ------
Preferred Primary: 2 numStoredReplicas: 2 numOldStoredReplicas: 0 distKey: 0 LogPartId: 0
------ Stored Replica ------
Replica node is: 2 initialGci: 2 numCrashedReplicas = 0 nextLcpNo = 1
LcpNo[0]: maxGciCompleted: 1 maxGciStarted: 2 lcpId: 1 lcpStatus: valid
```
25.5.20 ndb_print_schema_file — Print NDB Schema File Contents

ndb_print_schema_file obtains diagnostic information from a cluster schema file.

Usage

```
ndb_print_schema_file file_name
```

`file_name` is the name of a cluster schema file. For more information about cluster schema files, see NDB Cluster Data Node File System Directory.

Like ndb_print_backup_file and ndb_print_sys_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_schema_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

25.5.21 ndb_print_sys_file — Print NDB System File Contents

ndb_print_sys_file obtains diagnostic information from an NDB Cluster system file.

Usage

```
ndb_print_sys_file file_name
```

`file_name` is the name of a cluster system file (sysfile). Cluster system files are located in a data node’s data directory (DataDir); the path under this directory to system files matches the pattern `ndb_#_fs/D/#/DBDIH/P/#.sysfile`. In each case, the # represents a number (not necessarily the same number). For more information, see NDB Cluster Data Node File System Directory.

Like ndb_print_backup_file and ndb_print_schema_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_backup_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

25.5.22 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log
ndb_redo_log_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. ndb_redo_log_reader is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

The C++ source files for ndb_redo_log_reader can be found in the directory /storage/ndb/src/kernel/blocks/dblqh/redoLogReader.

Options that can be used with ndb_redo_log_reader are shown in the following table. Additional descriptions follow the table.

### Usage

```
ndb_redo_log_reader file_name [options]
```

- **file_name** is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (DataDir); the path under this directory to the redo log files matches the pattern `ndb_nodeid_fs/D#/DBLQH/S#/FragLog.nodeid` is the data node's node ID. The two instances of # each represent a number (not necessarily the same number); the number following D is in the range 8-39 inclusive; the range of the number following S varies according to the value of the `NoOfFragmentLogFiles` configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see NDB Cluster Data Node File System Directory.

The name of the file to be read may be followed by one or more of the options listed here:

- **-dump**

  Command-Line Format

  ```
  -dump
  ```

  Print dump info.

- **--file-key, -K**

  Command-Line Format

  ```
  --file-key=key
  ```

  Supply file decryption key using stdin, tty, or a my.cnf file.

- **--file-key-from-stdin**

  Command-Line Format

  ```
  --file-key-from-stdin
  ```

  Supply file decryption key using stdin.

- **-filedescriptors**

  Command-Line Format

  ```
  -filedescriptors
  ```

  -filedescriptors: Print file descriptors only.

- **--help**

  Command-Line Format

  ```
  --help
  ```

  --help: Print usage information.

- **-lap**

  Command-Line Format

  ```
  -lap
  ```

  Provide lap info, with max GCI started and completed.
**ndb_redo_log_reader — Check and Print Content of Cluster Redo Log**

- **Command-Line Format** `-mbyte #`  
  **Type** Numeric  
  **Default Value** 0  
  **Minimum Value** 0  
  **Maximum Value** 15  

  `-mbyte #`: Starting megabyte.  
  # is an integer in the range 0 to 15, inclusive.

- **Command-Line Format** `-mbyteheaders`  
  **-mbyteheaders**: Show only the first page header of every megabyte in the file.

- **Command-Line Format** `-noprint`  
  **-noprint**: Do not print the contents of the log file.

- **Command-Line Format** `-nocheck`  
  **-nocheck**: Do not check the log file for errors.

- **Command-Line Format** `-page #`  
  **Type** Integer  
  **Default Value** 0  
  **Minimum Value** 0  
  **Maximum Value** 31  

  `-page #`: Start at this page.  
  # is an integer in the range 0 to 31, inclusive.

- **Command-Line Format** `-pageheaders`  
  **-pageheaders**: Show page headers only.

- **Command-Line Format** `-pageindex #`  
  **Type** Integer  
  **Default Value** 12  
  **Minimum Value** 12  
  **Maximum Value** 8191  

  `-pageindex #`: Start at this page index.  
  # is an integer between 12 and 8191, inclusive.

- **-twiddle**  
  **Command-Line Format** `-twiddle`  
  Bit-shifted dump.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server)
ndb_redo_log_reader must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**25.5.23 ndb_restore — Restore an NDB Cluster Backup**

The NDB Cluster restoration program is implemented as a separate command-line utility ndb_restore, which can normally be found in the MySQL bin directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

ndb_restore must be executed once for each of the backup files that were created by the START BACKUP command used to create the backup (see Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”). This is equal to the number of data nodes in the cluster at the time that the backup was created.

---

**Note**

Before using ndb_restore, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 25.6.6, “NDB Cluster Single User Mode”, for more information.

Options that can be used with ndb_restore are shown in the following table. Additional descriptions follow the table.

- **--allow-pk-changes**

| Command-Line Format | --allow-pk-changes[=0|1] |
|---------------------|--------------------------|
| Type                | Integer                  |
| Default Value       | 0                        |
| Minimum Value       | 0                        |
| Maximum Value       | 1                        |

When this option is set to 1, ndb_restore allows the primary keys in a table definition to differ from that of the same table in the backup. This may be desirable when backing up and restoring between different schema versions with primary key changes on one or more tables, and it appears that performing the restore operation using ndb_restore is simpler or more efficient than issuing many ALTER TABLE statements after restoring table schemas and data.

The following changes in primary key definitions are supported by --allow-pk-changes:

- **Extending the primary key**: A non-nullable column that exists in the table schema in the backup becomes part of the table’s primary key in the database.

  **Important**

  When extending a table’s primary key, any columns which become part of primary key must not be updated while the backup is being taken; any such updates discovered by ndb_restore cause the restore operation to fail, even when no change in value takes place. In some cases, it may be possible to override this behavior using the --ignore-extended-pk-updates option; see the description of this option for more information.

- **Contracting the primary key (1)**: A column that is already part of the table’s primary key in the backup schema is no longer part of the primary key, but remains in the table.

- **Contracting the primary key (2)**: A column that is already part of the table’s primary key in the backup schema is removed from the table entirely.
These differences can be combined with other schema differences supported by `ndb_restore`, including changes to blob and text columns requiring the use of staging tables.

Basic steps in a typical scenario using primary key schema changes are listed here:

1. Restore table schemas using `ndb_restore --restore-meta`
2. Alter schema to that desired, or create it
3. Back up the desired schema
4. Run `ndb_restore --disable-indexes` using the backup from the previous step, to drop indexes and constraints
5. Run `ndb_restore --allow-pk-changes` (possibly along with `--ignore-extended-pk-updates`, `--disable-indexes`, and possibly other options as needed) to restore all data
6. Run `ndb_restore --rebuild-indexes` using the backup made with the desired schema, to rebuild indexes and constraints

When extending the primary key, it may be necessary for `ndb_restore` to use a temporary secondary unique index during the restore operation to map from the old primary key to the new one. Such an index is created only when necessary to apply events from the backup log to a table which has an extended primary key. This index is named `NDB$RESTORE_PK_MAPPING`, and is created on each table requiring it; it can be shared, if necessary, by multiple instances of `ndb_restore` instances running in parallel. (Running `ndb_restore --rebuild-indexes` at the end of the restore process causes this index to be dropped.)

* `--append`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--append</th>
</tr>
</thead>
</table>

When used with the `--tab` and `--print-data` options, this causes the data to be appended to any existing files having the same names.

* `--backup-path=dir_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--backup-path=path</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Directory name</th>
</tr>
</thead>
</table>

| Default Value   | ./                 |

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup-path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup-path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each storage node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to
nb_restore — Restore an NDB Cluster Backup

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 8.4.0 to a cluster running NDB Cluster 8.0.38, you must use the `ndb_restore` that comes with the NDB Cluster 8.0.38 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

- `--backup-password=password`

  This option specifies a password to be used when decrypting an encrypted backup with the `--decrypt` option. This must be the same password that was used to encrypt the backup.

  The password must be 1 to 256 characters in length, and must be enclosed by single or double quotation marks. It can contain any of the ASCII characters having character codes 32, 35, 38, 40-91, 93, 95, and 97-126; in other words, it can use any printable ASCII characters except for !, ', "", $, %, \, and ^.

  It is possible to omit the password, in which case `ndb_restore` waits for it to be supplied from `stdin`, as when using `--backup-password-from-stdin`.

- `--backup-password-from-stdin=[TRUE|FALSE]`

  When used in place of `--backup-password`, this option enables input of the backup password from the system shell (`stdin`), similar to how this is done when supplying the password interactively to `mysql` when using `--password` without supplying the password on the command line.

- `--backupid=#, -b`

  This option is required; it is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message.
ndb_restore — Restore an NDB Cluster Backup

message displayed upon completion of a backup. (See Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”.)

Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups results at best in restoring the cluster to an inconsistent state, and is likely to fail altogether.

• --character-sets-dir

Command-Line Format

```
--character-sets-dir=path
```

Directory containing character sets.

• --connect, -c

Command-Line Format

```
--connect=connection_string
```

Type

String

Default Value

localhost:1186

Alias for --ndb-connectstring.

• --connect-retries

Command-Line Format

```
--connect-retries=#
```

Type

Integer

Default Value

12

Minimum Value

0

Maximum Value

12

Number of times to retry connection before giving up.

• --connect-retry-delay

Command-Line Format

```
--connect-retry-delay=#
```

Type

Integer

Default Value

5

Minimum Value

0

Maximum Value

5

Number of seconds to wait between attempts to contact management server.

• --connect-string

Command-Line Format

```
--connect-string=connection_string
```

Type

String

Default Value

[none]

Same as --ndb-connectstring.

• --core-file

Command-Line Format

```
--core-file
```

Write core file on error; used in debugging.

- **--decrypt**

  Command-Line Format  
  ```
  --decrypt
  ```

  Decrypt an encrypted backup using the password supplied by the `--backup-password` option.

- **--defaults-extra-file**

  Command-Line Format  
  ```
  --defaults-extra-file=path
  ```

  Type  
  String

  Default Value  
  `[none]`

  Read given file after global files are read.

- **--defaults-file**

  Command-Line Format  
  ```
  --defaults-file=path
  ```

  Type  
  String

  Default Value  
  `[none]`

  Read default options from given file only.

- **--defaults-group-suffix**

  Command-Line Format  
  ```
  --defaults-group-suffix=string
  ```

  Type  
  String

  Default Value  
  `[none]`

  Also read groups with `concat(group, suffix)`.

- **--disable-indexes**

  Command-Line Format  
  ```
  --disable-indexes
  ```

  Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

  This option also drops any foreign keys specified in the backup.

  MySQL can open an NDB table for which one or more indexes cannot be found, provided the query does not use any of the affected indexes; otherwise the query is rejected with `ER_NOT_KEYFILE`. In the latter case, you can temporarily work around the problem by executing an `ALTER TABLE` statement such as this one:

  ```
  ALTER TABLE tbl ALTER INDEX idx INVISIBLE;
  ```

  This causes MySQL to ignore the index `idx` on table `tbl`. See Primary Keys and Indexes, for more information, as well as Section 10.3.12, “Invisible Indexes”.

  4168
### ndb_restore — Restore an NDB Cluster Backup

- **--dont-ignore-systab-0, --f**

**Command-Line Format**

```
--dont-ignore-systab-0
```

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. **--dont-ignore-systab-0** causes the system table to be restored. This option is intended for experimental and development use only, and is not recommended in a production environment.

- **--exclude-databases=**

**Command-Line Format**

```
--exclude-databases=list
```

**Type** String

**Default Value**

Comma-delimited list of one or more databases which should not be restored.

This option is often used in combination with **--exclude-tables**; see that option's description for further information and examples.

- **--exclude-intermediate-sql-tables[=TRUE|FALSE]**

**Command-Line Format**

```
--exclude-intermediate-sql-tables[=TRUE|FALSE]
```

**Type** Boolean

**Default Value** TRUE

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When **TRUE**, the **--exclude-intermediate-sql-tables** option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is **TRUE** by default.

- **--exclude-missing-columns**

**Command-Line Format**

```
--exclude-missing-columns
```

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the **include-* or --exclude-*** options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- **--exclude-missing-tables**

**Command-Line Format**

```
--exclude-missing-tables
```

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

- **--exclude-tables=**

**Command-Line Format**

```
--exclude-tables=list
```

**Type** String

4169
Default Value

List of one or more tables to exclude; each table reference must include the database name. Often used together with --exclude-databases.

When --exclude-databases or --exclude-tables is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by ndb_restore.

This table shows several invocations of ndb_restore using --exclude-* options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

Table 25.23 Several invocations of ndb_restore using --exclude-* options, and the effects these options have on restoring from an NDB Cluster backup.

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>--exclude-databases=db1</td>
<td>All tables in all databases except db1 are restored; no tables in db1 are restored</td>
</tr>
<tr>
<td>--exclude-databases=db1,db2 (or --exclude-databases=db1 --exclude-databases=db2)</td>
<td>All tables in all databases except db1 and db2 are restored; no tables in db1 or db2 are restored</td>
</tr>
<tr>
<td>--exclude-tables=db1.t1</td>
<td>All tables except t1 in database db1 are restored; all other tables in db1 are restored; all tables in all other databases are restored</td>
</tr>
<tr>
<td>--exclude-tables=db1.t2,db2.t1 (or --exclude-tables=db1.t2 --exclude-tables=db2.t1)</td>
<td>All tables in database db1 except for t2 and all tables in database db2 except for table t1 are restored; no other tables in db1 or db2 are restored; all tables in all other databases are restored</td>
</tr>
</tbody>
</table>

You can use these two options together. For example, the following causes all tables in all databases except for databases db1 and db2, and tables t1 and t2 in database db3, to be restored:

```
$> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use --include-* and --exclude-* options together, subject to the following rules:

- The actions of all --include-* and --exclude-* options are cumulative.
- All --include-* and --exclude-* options are evaluated in the order passed to ndb_restore, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table "wins".

For example, the following set of options causes ndb_restore to restore all tables from database db1 except db1.t1, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database db1 to be restored (including db1.t1, but no tables from any other database), because the --include-databases option, being farthest to the right, is the first match against database db1 and thus takes precedence over any other option that matches db1 or any tables in db1:

```
--exclude-tables=db1.t1 --include-databases=db1
```
• **--fields-enclosed-by=char**

  Command-Line Format  
  \(--fields-enclosed-by=char\)

  Type  
  String

  Default Value

  Each column value is enclosed by the string passed to this option (regardless of data type; see the description of **--fields-optionally-enclosed-by**).

• **--fields-optionally-enclosed-by**

  Command-Line Format  
  \(--fields-optionally-enclosed-by\)

  Type  
  String

  Default Value

  The string passed to this option is used to enclose column values containing character data (such as **CHAR**, **VARCHAR**, **BINARY**, **TEXT**, or **ENUM**).

• **--fields-terminated-by=char**

  Command-Line Format  
  \(--fields-terminated-by=char\)

  Type  
  String

  Default Value  
  \t (tab)

  The string passed to this option is used to separate column values. The default value is a tab character (\t).

• **--help**

  Command-Line Format  
  \(--help\)

  Display help text and exit.

• **--hex**

  Command-Line Format  
  --hex

  If this option is used, all binary values are output in hexadecimal format.

• **--ignore-extended-pk-updates**

  Command-Line Format  
  --ignore-extended-pk-updates[=0|1]

  Type  
  Integer

  Default Value  
  0

  Minimum Value  
  0

  Maximum Value  
  1

  When using **--allow-pk-changes**, columns which become part of a table's primary key must not be updated while the backup is being taken; such columns should keep the same values from the time values are inserted into them until the rows containing the values are deleted. If **ndb_restore** encounters updates to these columns when restoring a backup, the restore fails. Because some applications may set values for all columns when updating a row, even when some column values are not changed, the backup may include log events appearing to update columns which are not in fact modified. In such cases you can set **--ignore-extended-pk-updates** to 1, forcing **ndb_restore** to ignore such updates.
**Important**

When causing these updates to be ignored, the user is responsible for ensuring that there are no updates to the values of any columns that become part of the primary key.

For more information, see the description of `--allow-pk-changes`.

* --include-databases=\*db-list\*

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--include-databases=list</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>Comma-delimited list of one or more databases to restore. Often used together with <code>--include-tables</code>; see the description of that option for further information and examples.</td>
</tr>
</tbody>
</table>

* --include-stored-grants

`ndb_restore` does not by default restore shared users and grants (see Section 25.6.13, “Privilege Synchronization and NDB_STORED_USER”) to the `ndb_sql_metadata` table. Specifying this option causes it to do so.

* --include-tables=\*table-list\*

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--include-tables=list</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>Comma-delimited list of tables to restore; each table reference must include the database name.</td>
</tr>
</tbody>
</table>

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-\*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

**Table 25.24 Several invocations of ndb_restore using --include-* options, and their effects on restoring from an NDB Cluster backup.**

<table>
<thead>
<tr>
<th><strong>Option</strong></th>
<th><strong>Result</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--include-databases=db1</code></td>
<td>Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 --include-databases=db2</code>)</td>
<td>Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><code>--include-tables=db1.t1</code></td>
<td>Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored</td>
</tr>
<tr>
<td><code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 --include-tables=db2.t1</code>)</td>
<td>Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code>, <code>db2</code>, or any other database are restored</td>
</tr>
</tbody>
</table>
You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```bash
$> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any `--include-` (or `--exclude-`) options, using the syntax shown here:

```bash
ndb_restore other_options db_name[,db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

---

**Command-Line Format**

---

### `--lines-terminated-by=char`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td><code>\n</code> (linebreak)</td>
</tr>
</tbody>
</table>

Specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- **--login-path**

  ```bash
  Command-Line Format  --login-path=path
  Type      String
  Default Value [none]
  ```

  Read given path from login file.

- **--no-login-paths**

  ```bash
  Command-Line Format  --no-login-paths
  ```

  Skips reading options from the login path file.

- **--lossy-conversions, -L**

  ```bash
  Command-Line Format  --lossy-conversions
  ```

  This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

  This option also makes it possible to restore a `NULL` column as `NOT NULL`. The column must not contain any `NULL` entries; otherwise `ndb_restore` stops with an error.

  `ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.
### ndb_restore — Restore an NDB Cluster Backup

- **--no-binlog**
  
  **Command-Line Format**
  ```
  --no-binlog
  ```

  This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

- **--no-restore-disk-objects, -d**
  
  **Command-Line Format**
  ```
  --no-restore-disk-objects
  ```

  This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see Section 25.6.11, “NDB Cluster Disk Data Tables”, for more information about these.

- **--no-upgrade, -u**
  
  **Command-Line Format**
  ```
  --no-upgrade
  ```

  When using `ndb_restore` to restore a backup, `VARCHAR` columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying `--no-upgrade`.

- **--ndb-connectstring**
  
  **Command-Line Format**
  ```
  --ndb-connectstring=connection_string
  ```

  **Type** String
  
  **Default Value** [none]

- **--ndb-mgm-tls**
  
  **Command-Line Format**
  ```
  --ndb-mgm-tls=level
  ```

  **Type** Enumeration
  
  **Default Value** relaxed
  
  **Valid Values**
  - relaxed
  - strict

  Sets the level of TLS support required to connect to the management server; one of relaxed or `strict`. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

- **--ndb-mgmd-host**
  
  **Command-Line Format**
  ```
  --ndb-mgmd-host=connection_string
  ```

  **Type** String
  
  **Default Value** [none]

  Same as `--ndb-connectstring`.

- **--ndb-nodegroup-map=map, -z**
  
  **Command-Line Format**
  ```
  --ndb-nodegroup-map=map
  ```
Any value set for this option is ignored, and the option itself does nothing.

- **--ndb-nodeid**

Command-Line Format: `--ndb-nodeid=#`

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- **--ndb-optimized-node-selection**

Command-Line Format: `--ndb-optimized-node-selection`

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- **--ndb-tls-search-path**

Command-Line Format: `--ndb-tls-search-path=list`

<table>
<thead>
<tr>
<th>Type</th>
<th>Path name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value (Unix)</td>
<td>$HOME/ndb-tls</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td>$HOMEDIR/ndb-tls</td>
</tr>
</tbody>
</table>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (`:`); on Windows systems, the semicolon character (`;`) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (`$`), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (`.`) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- **--no-defaults**

Command-Line Format: `--no-defaults`

Do not read default options from any option file other than login file.

- **--nodeid=#, -n**

Command-Line Format: `--nodeid=#`

<table>
<thead>
<tr>
<th>Type</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

Specify the node ID of the data node on which the backup was taken; required.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See Restoring to a different number of data nodes, for additional information and examples.
**ndb_restore** — Restore an NDB Cluster Backup

- **--num-slices=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--num-slices=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

When restoring a backup by slices, this option sets the number of slices into which to divide the backup. This allows multiple instances of **ndb_restore** to restore disjoint subsets in parallel, potentially reducing the amount of time required to perform the restore operation.

A *slice* is a subset of the data in a given backup; that is, it is a set of fragments having the same slice ID, specified using the **--slice-id** option. The two options must always be used together, and the value set by **--slice-id** must always be less than the number of slices.

**ndb_restore** encounters fragments and assigns each one a fragment counter. When restoring by slices, a slice ID is assigned to each fragment; this slice ID is in the range 0 to 1 less than the number of slices. For a table that is not a **BLOB** table, the slice to which a given fragment belongs is determined using the formula shown here:

$$ [\text{slic}_\text{e ID}] = [\text{fragment counter}] \mod [\text{number of slices}] $$

For a **BLOB** table, a fragment counter is not used; the fragment number is used instead, along with the ID of the main table for the **BLOB** table (recall that **NDB** stores **BLOB** values in a separate table internally). In this case, the slice ID for a given fragment is calculated as shown here:

$$ [\text{slic}_\text{e ID}] = ([\text{main table ID}] + [\text{fragment ID}]) \mod [\text{number of slices}] $$

Thus, restoring by *N* slices means running *N* instances of **ndb_restore**, all with **--num-slices=N** (along with any other necessary options) and one each with **--slice-id=1**, **--slice-id=2**, **--slice-id=3**, and so on through **slice-id=N-1**.

**Example.** Assume that you want to restore a backup named **BACKUP-1**, found in the default directory `/var/lib/mysql-cluster/BACKUP/BACKUP-1` on the node file system on each data node, to a cluster with four data nodes having the node IDs 1, 2, 3, and 4. To perform this operation using five slices, execute the sets of commands shown in the following list:

1. Restore the cluster metadata using **ndb_restore** as shown here:

   ```
   $> ndb_restore -b 1 -n 1 -m --disable-indexes --backup-path=/home/ndbuser/backups
   ```

2. Restore the cluster data to the data nodes invoking **ndb_restore** as shown here:

   ```
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_resume -b 1 -n 2 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_resume -b 1 -n 2 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_resume -b 1 -n 3 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_resume -b 1 -n 3 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_resume -b 1 -n 3 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_resume -b 1 -n 3 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   $> ndb_resume -b 1 -n 3 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/Ba
   ```
ndb_restore — Restore an NDB Cluster Backup

All of the commands just shown in this step can be executed in parallel, provided there are enough slots for connections to the cluster (see the description for the --backup-path option).

3. Restore indexes as usual, as shown here:

```bash
$> ndb_restore -b 1 -n 1 --rebuild-indexes --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

4. Finally, restore the epoch, using the command shown here:

```bash
$> ndb_restore -b 1 -n 1 --restore-epoch --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

You should use slicing to restore the cluster data only; it is not necessary to employ --num-slices or --slice-id when restoring the metadata, indexes, or epoch information. If either or both of these options are used with the ndb_restore options controlling restoration of these, the program ignores them.

The effects of using the --parallelism option on the speed of restoration are independent of those produced by slicing or parallel restoration using multiple instances of ndb_restore (--parallelism specifies the number of parallel transactions executed by a single ndb_restore thread), but it can be used together with either or both of these. You should be aware that increasing --parallelism causes ndb_restore to impose a greater load on the cluster; if the system can handle this, restoration should complete even more quickly.

The value of --num-slices is not directly dependent on values relating to hardware such as number of CPUs or CPU cores, amount of RAM, and so forth, nor does it depend on the number of LDMs.

It is possible to employ different values for this option on different data nodes as part of the same restoration; doing so should not in and of itself produce any ill effects.

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--parallelism=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>128</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

ndb_restore uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of ndb_restore tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the .Data file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.
ndb_restore — Restore an NDB Cluster Backup

- **--preserve-trailing-spaces, -P**

**Command-Line Format**  
**--preserve-trailing-spaces**

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

**Note**

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

- **--print**

**Command-Line Format**  
**--print**

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print-data`, `--print-meta`, and `--print-log` options together.

**Note**

Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to an NDB Cluster.

- **--print-data**

**Command-Line Format**  
**--print-data**

Cause `ndb_restore` to direct its output to `stdout`. Often used together with one or more of `--tab`, `--fields-enclosed-by`, `--fields-optionally-enclosed-by`, `--fields-terminated-by`, `--hex`, and `--append`.

TEXT and BLOB column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using `--print-data`.

- **--print-defaults**

**Command-Line Format**  
**--print-defaults**

Print program argument list and exit.

- **--print-log**

**Command-Line Format**  
**--print-log**

Cause `ndb_restore` to output its log to `stdout`.

- **--print-meta**

**Command-Line Format**  
**--print-meta**

Print all metadata to `stdout`.

4178
**print-sql-log**

**Command-Line Format**  
--print-sql-log

Log SQL statements to stdout. Use the option to enable; normally this behavior is disabled. The option checks before attempting to log whether all the tables being restored have explicitly defined primary keys; queries on a table having only the hidden primary key implemented by NDB cannot be converted to valid SQL.

This option does not work with tables having BLOB columns.

**--progress-frequency=N**

**Command-Line Format**  
--progress-frequency=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Print a status report each $N$ seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

**--promote-attributes, -A**

ndb_restore supports limited attribute promotion in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a CHAR(20) column can be restored to a column declared as VARCHAR(20), VARCHAR(30), or CHAR(30); data from a MEDIUMINT column can be restored to a column of type INT or BIGINT. See Replication of Columns Having Different Data Types, for a table of type conversions currently supported by attribute promotion.

This option also makes it possible to restore a NOT NULL column as NULL.

Attribute promotion by ndb_restore must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. ndb_restore cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using ALTER TABLE after restoring the table metadata but before restoring the data.

2. Invoke ndb_restore with the --promote-attributes option (short form -A) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

When converting between character data types and TEXT or BLOB, only conversions between character types (CHAR and VARCHAR) and binary types (BINARY and VARBINARY) can be performed at the same time. For example, you cannot promote an INT column to BIGINT while promoting a VARCHAR column to TEXT in the same invocation of ndb_restore.

Converting between TEXT columns using different character sets is not supported, and is expressly disallowed.

When performing conversions of character or binary types to TEXT or BLOB with ndb_restore, you may notice that it creates and uses one or more staging tables named table_name$STnode_i.
These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

- **--rebuild-indexes**

  **Command-Line Format**

  ```
  --rebuild-indexes
  ```

  Enable multithreaded rebuilding of the ordered indexes while restoring a native NDB backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

  It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

  Building of ordered indices is parallelized with the number of LDMs by default.Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

  Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore` `--rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore` `--rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

- **--remap-column=db.tbl.col:fn:args**

  **Command-Line Format**

  ```
  --remap-column=string
  ```

  **Type**
  String

  **Default Value**
  [none]

  When used together with `--restore-data`, this option applies a function to the value of the indicated column. Values in the argument string are listed here:

  - **db**: Database name, following any renames performed by `--rewrite-database`.
  - **tbl**: Table name.
  - **col**: Name of the column to be updated. This column must be of type INT or BIGINT. The column can also be but is not required to be UNSIGNED.
  - **fn**: Function name; currently, the only supported name is offset.
  - **args**: Arguments supplied to the function. Currently, only a single argument, the size of the offset to be added by the offset function, is supported. Negative values are supported. The size of the argument passed to the offset function is limited to `-2147483648` to `2147483647` (see Section 13.1.2, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”).

  If applying the offset value to the column would cause an overflow or underflow, the restore operation fails. This could happen, for example, if the column is a BIGINT, and the option
attempts to apply an offset value of 8 on a row in which the column value is 4294967291, since 4294967291 + 8 = 4294967299 > 4294967295.

This option can be useful when you wish to merge data stored in multiple source instances of NDB Cluster (all using the same schema) into a single destination NDB Cluster, using NDB native backup (see Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”) and ndb_restore to merge the data, where primary and unique key values are overlapping between source clusters, and it is necessary as part of the process to remap these values to ranges that do not overlap. It may also be necessary to preserve other relationships between tables. To fulfill such requirements, it is possible to use the option multiple times in the same invocation of ndb_restore to remap columns of different tables, as shown here:

```bash
$> ndb_restore --restore-data --remap-column=hr.employee.id:offset:1000 \
--remap-column=hr.manager.id:offset:1000 --remap-column=hr.firstaiders.id:offset:1000
```

(Other options not shown here may also be used.)

--remap-column can also be used to update multiple columns of the same table. Combinations of multiple tables and columns are possible. Different offset values can also be used for different columns of the same table, like this:

```bash
$> ndb_restore --restore-data --remap-column=hr.employee.salary:offset:10000 \
--remap-column=hr.employee.hours:offset:-10
```

When source backups contain duplicate tables which should not be merged, you can handle this by using --exclude-tables, --exclude-databases, or by some other means in your application.

Information about the structure and other characteristics of tables to be merged can obtained using SHOW CREATE TABLE; the ndb_desc tool; and MAX(), MIN(), LAST_INSERT_ID(), and other MySQL functions.

Replication of changes from merged to unmerged tables, or from unmerged to merged tables, in separate instances of NDB Cluster is not supported.

• --restore-data, -r

Command-Line Format --restore-data

Output NDB table data and logs.

• --restore-epoch, -e

Command-Line Format --restore-epoch

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replica. When this option is used, the row in the mysql.ndb_apply_status having 0 in the id column is updated if it already exists; such a row is inserted if it does not already exist. (See Section 25.7.9, “NDB Cluster Backups With NDB Cluster Replication”.)

• --restore-meta, -m

Command-Line Format --restore-meta

This option causes ndb_restore to print NDB table metadata.

The first time you run the ndb_restore restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the --
ndb_restore — Restore an NDB Cluster Backup

### restore-meta (-m) option

Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

ndb_restore uses the default number of partitions for the target cluster, unless the number of local data manager threads is also changed from what it was for data nodes in the original cluster.

When using this option, it is recommended that auto synchronization be disabled by setting ndb_metadata_check=OFF until ndb_restore has completed restoring the metadata, after which it can it turned on again to synchronize objects newly created in the NDB dictionary.

#### Note

The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with --initial prior to performing the restore.)

- **--restore-privilege-tables**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--restore-privilege-tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
</tbody>
</table>

No longer used.

- **--rewrite-database=olddb,newdb**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--rewrite-database=string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named products, you can restore the data it contains to a database named inventory, use this option as shown here (omitting any other options that might be required):

```bash
$> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of ndb_restore. Thus it is possible to restore simultaneously from a database named db1 to a database named db2 and from a database named db3 to one named db4 using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`.

Other ndb_restore options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored.

It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases db1 and db2 into database db3.

#### Important

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.
• **--skip-broken-objects**

Command-Line Format: **--skip-broken-objects**

This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the **--skip-broken-objects** option works only in the case of missing blob parts tables.

• **--skip-table-check, -s**

Command-Line Format: **--skip-table-check**

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options **--skip-table-check** or **--promote-attributes** is in use. These differences in column definitions are of the following types:

- Different COLUMN_FORMAT settings (**FIXED, DYNAMIC, DEFAULT**)
- Different STORAGE settings (**MEMORY, DISK**)
- Different default values
- Different distribution key settings

• **--skip-unknown-objects**

Command-Line Format: **--skip-unknown-objects**

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.6 to a cluster running NDB Cluster 7.5.

• **--slice-id=#**

Command-Line Format: **--slice-id=#**

<table>
<thead>
<tr>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1023</td>
</tr>
</tbody>
</table>

When restoring by slices, this is the ID of the slice to restore. This option is always used together with **--num-slices**, and its value must be always less than that of **--num-slices**.

For more information, see the description of the **--num-slices** elsewhere in this section.

• **--tab=dir_name, -T dir_name**

Command-Line Format: **--tab=path**
ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Type</th>
<th>Directory name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Causes --print-data to create dump files, one per table, each named tbl_name.txt. It requires as its argument the path to the directory where the files should be saved; use . for the current directory.</td>
<td></td>
</tr>
</tbody>
</table>

- --timestamp-printouts

Command-Line Format: `--timestamp-printouts{=true|false}`

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>true</td>
</tr>
</tbody>
</table>

Causes info, error, and debug log messages to be prefixed with timestamps.

This option is enabled by default. Disable it with `--timestamp-printouts=false`.

- --usage

Command-Line Format: `--usage`

Display help text and exit; same as `--help`.

- --verbose=

Command-Line Format: `--verbose=#`

<table>
<thead>
<tr>
<th>Type</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

- --version

Command-Line Format: `--version`

Display version information and exit.

- --with-apply-status

Command-Line Format: `--with-apply-status`

Restore all rows from the backup's ndb_apply_status table (except for the row having server_id = 0, which is generated using --restore-epoch). This option requires that --restore-data also be used.

If the ndb_apply_status table from the backup already contains a row with server_id = 0, ndb_restore --with-apply-status deletes it. For this reason, we recommend that you use ndb_restore --restore-epoch after invoking ndb_restore with the --with-apply-status option. You can also use --restore-epoch concurrently with the last of any invocations of ndb_restore --with-apply-status used to restore the cluster.

For more information, see ndb_apply_status Table.
Normally, when restoring from an NDB Cluster backup, \texttt{ndb\_restore} requires at a minimum the \texttt{--nodeid} (short form: \texttt{-n}), \texttt{--backupid} (short form: \texttt{-b}), and \texttt{--backup-path} options.

The \texttt{-c} option is used to specify a connection string which tells \texttt{ndb\_restore} where to locate the cluster management server (see Section 25.4.3.3, “NDB Cluster Connection Strings”). If this option is not used, then \texttt{ndb\_restore} attempts to connect to a management server on \texttt{localhost:1186}. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one \texttt{[api]} or \texttt{[mysqld]} section that can be used by it in the cluster \texttt{config.ini} file. It is a good idea to keep at least one empty \texttt{[api]} or \texttt{[mysqld]} section in \texttt{config.ini} that is not being used for a MySQL server or other application for this reason (see Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”).

\texttt{ndb\_restore} can decrypt an encrypted backup using \texttt{--decrypt} and \texttt{--backup-password}. Both options must be specified to perform decryption. See the documentation for the \texttt{START BACKUP} management client command for information on creating encrypted backups.

You can verify that \texttt{ndb\_restore} is connected to the cluster by using the \texttt{SHOW} command in the \texttt{ndb\_mgm} management client. You can also accomplish this from a system shell, as shown here:

\begin{verbatim}
$> ndb_mgm -e "SHOW"
\end{verbatim}

\textbf{Error reporting.}

\texttt{ndb\_restore} reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them, and reports \texttt{Restore successful, but encountered temporary error, please look at configuration} in such cases.

\begin{itemize}
  \item \textbf{Important}
  \end{itemize}

After using \texttt{ndb\_restore} to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replica are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a \texttt{SHOW TABLES} statement on that SQL node before running \texttt{START REPLICA}. This is a known issue in NDB Cluster.

### 25.5.24 \texttt{ndb\_secretsfile\_reader} — Obtain Key Information from an Encrypted NDB Data File

\texttt{ndb\_secretsfile\_reader} gets the encryption key from an \texttt{NDB} encryption secrets file, given the password.

#### Usage

\begin{verbatim}
ndb\_secretsfile\_reader options file
\end{verbatim}

The \texttt{options} must include one of \texttt{--filesystem-password} or \texttt{--filesystem-password-from-stdin}, and the encryption password must be supplied, as shown here:

\begin{verbatim}
> ndb\_secretsfile\_reader --filesystem-password=54kl14 ndb\_5\_fs/D1/NDBCNTR/S0\_sysfile
ndb\_secretsfile\_reader: [Warning] Using a password on the command line interface can be insecure. cac256e18b2ddf6b5ef82d99a72f18e864b78453cc7fa40bfa0c40b91122d18
\end{verbatim}

These and other options that can be used with \texttt{ndb\_secretsfile\_reader} are shown in the following table. Additional descriptions follow the table.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{Command-Line Format} & \textbf{Description} \\
\hline
\texttt{--defaults-extra-file} & \\
\hline
\end{tabular}
\end{table}
**ndb_secretsfile_reader** — Obtain Key Information from an Encrypted NDB Data File

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read given file after global files are read.</td>
<td>[none]</td>
</tr>
</tbody>
</table>

- **--defaults-file**

  **Command-Line Format**

  `--defaults-file=path`

  **Type**

  String

  **Default Value**

  [none]

  Read default options from given file only.

- **--defaults-group-suffix**

  **Command-Line Format**

  `--defaults-group-suffix=string`

  **Type**

  String

  **Default Value**

  [none]

  Also read groups with `concat(group, suffix)`.

- **--filesystem-password**

  **Command-Line Format**

  `--filesystem-password=password`

  Pass the filesystem encryption and decryption password to `ndb_secretsfile_reader` using `stdin`, `tty`, or the `my.cnf` file.

- **--filesystem-password-from-stdin**

  **Command-Line Format**

  `--filesystem-password-from-stdin={TRUE|FALSE}`

  Pass the filesystem encryption and decryption password to `ndb_secretsfile_reader` from `stdin` (only).

- **--help**

  **Command-Line Format**

  `--help`

  Display help text and exit.

- **--login-path**

  **Command-Line Format**

  `--login-path=path`

  **Type**

  String

  **Default Value**

  [none]

  Read given path from login file.

- **--no-login-paths**

  **Command-Line Format**

  `--no-login-paths`

  Skips reading options from the login path file.

- **--no-defaults**
ndb_select_all — Print Rows from an NDB Table

Command-Line Format

--no-defaults

Do not read default options from any option file other than login file.

•  --print-defaults

Command-Line Format

--print-defaults

Print program argument list and exit.

•  --usage

Command-Line Format

--usage

Display help text and exit; same as --help.

•  --version

Command-Line Format

--version

Display version information and exit.

25.5.25 ndb_select_all — Print Rows from an NDB Table

ndb_select_all prints all rows from an NDB table to stdout.

Usage

ndb_select_all -c connection_string -d db_name [-> file_name]

Options that can be used with ndb_select_all are shown in the following table. Additional descriptions follow the table.

•  --character-sets-dir

Command-Line Format

--character-sets-dir=path

Directory containing character sets.

•  --connect-retries

Command-Line Format

--connect-retries=#

Type: Integer

Default Value: 12
Minimum Value: 0
Maximum Value: 12

Number of times to retry connection before giving up.

•  --connect-retry-delay

Command-Line Format

--connect-retry-delay=#

Type: Integer

Default Value: 5
Minimum Value: 0
Maximum Value

Number of seconds to wait between attempts to contact management server.

- **--connect-string**

  Command-Line Format: `--connect-string=connection_string`
  
  Type: String
  
  Default Value: [none]
  
  Same as `--ndb-connectstring`.

- **--core-file**

  Command-Line Format: `--core-file`
  
  Write core file on error; used in debugging.

- **--database=dbname, -d dbname**

  Name of the database in which the table is found. The default value is `TEST_DB`.

- **--descending, -z**

  Sorts the output in descending order. This option can be used only in conjunction with the `-o (--order) option`.

- **--defaults-extra-file**

  Command-Line Format: `--defaults-extra-file=path`
  
  Type: String
  
  Default Value: [none]
  
  Read given file after global files are read.

- **--defaults-file**

  Command-Line Format: `--defaults-file=path`
  
  Type: String
  
  Default Value: [none]
  
  Read default options from given file only.

- **--defaults-group-suffix**

  Command-Line Format: `--defaults-group-suffix=string`
  
  Type: String
  
  Default Value: [none]
  
  Also read groups with concat(group, suffix).

- **--delimiter=character, -D character**

  Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.
  
  The default delimiter is the tab character.
ndb_select_all — Print Rows from an NDB Table

- **--disk**
  Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- **--gci**
  Adds a GCI column to the output showing the global checkpoint at which each row was last updated. See Section 25.2, “NDB Cluster Overview”, and Section 25.6.3.2, “NDB Cluster Log Events”, for more information about checkpoints.

- **--gci64**
  Adds a $ROW$GCI64 column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- **--help**
  Display help text and exit.

- **--lock=lock_type, -l lock_type**
  Employs a lock when reading the table. Possible values for lock_type are:
  - **0**: Read lock
  - **1**: Read lock with hold
  - **2**: Exclusive read lock
  There is no default value for this option.

- **--login-path**
  Read given path from login file.

- **--no-login-paths**
  Skips reading options from the login path file.

- **--header=FALSE**
  Excludes column headers from the output.

- **--nodata**
  Causes any table data to be omitted.

- **--ndb-connectstring**
  Connects to the NDB cluster.
ndb_select_all — Print Rows from an NDB Table

Default Value

Set connection string for connecting to ndb_mgmd. Syntax: [nodeid=id;]
[host=hostname[:port]. Overrides entries in NDB_CONNECTSTRING and my.cnf.

• --ndb-mgm-tls

Command-Line Format
--ndb-mgm-tls=level
Type Enumeration
Default Value relaxed
Valid Values relaxed
strict

Sets the level of TLS support required to connect to the management server; one of relaxed or
strict. relaxed (the default) means that a TLS connection is attempted, but success is not
required; strict means that TLS is required to connect.

• --ndb-mgmd-host

Command-Line Format
--ndb-mgmd-host=connection_string
Type String
Default Value [none]

Same as --ndb-connectstring.

• --ndb-nodeid

Command-Line Format
--ndb-nodeid=#
Type Integer
Default Value [none]

Set node ID for this node, overriding any ID set by --ndb-connectstring.

• --ndb-optimized-node-selection

Command-Line Format
--ndb-optimized-node-selection

Enable optimizations for selection of nodes for transactions. Enabled by default; use
--skip-ndb-optimized-node-selection to disable.

• --ndb-tls-search-path

Command-Line Format
--ndb-tls-search-path=list
Type Path name
Default Value (Unix) $HOME/ndb-tls
Default Value (Windows) $HOMEDIR/ndb-tls

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are
separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator.
A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using --DWITH_NDB_TLS_SEARCH_PATH.

**Command-Line Format**

---

---no-defaults

Do not read default options from any option file other than login file.

---order=index_name, -o index_name

Orders the output according to the index named index_name.

**Note**

This is the name of an index, not of a column; the index must have been explicitly named when created.

---parallelism=#, -p #

Specifies the degree of parallelism.

---print-defaults

Print program argument list and exit.

---rowid

Adds a ROWID column providing information about the fragments in which rows are stored.

---tupscan, -t

Scan the table in the order of the tuples.

---usage

Display help text and exit; same as --help.

---useHexFormat -x

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

---version

Display version information and exit.
Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
| id | name      |
+----+-----------+
|  3 | shark     |
|  6 | puffer    |
|  2 | tuna      |
|  4 | manta ray |
|  5 | grouper   |
|  1 | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
$> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
```

All string values are enclosed by square brackets ([...]) in the output of `ndb_select_all`. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (  
id INT(11) NOT NULL AUTO_INCREMENT,  
nname VARCHAR(25) NOT NULL,  
bname VARCHAR(50) NOT NULL,  
PRIMARY KEY pk (id),  
KEY ix (name)
)  
TABLESPACE ts STORAGE DISK  
ENGINE=NDBCLUSTER;
```

This demonstrates the use of several additional `ndb_select_all` options:

```
$> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI id name      breed     DISK_REF
834461 2 [Scooby-Doo] [Great Dane] [m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834463 3 [Rin-Tin-Tin] [Alsatian] [m_file_no: 0 m_page: 34 m_page_idx: 0 ]
834461 4 [Rosscoe]    [Mutt]     [m_file_no: 0 m_page: 66 m_page_idx: 0 ]
834878 1 [Lassie]     [Collie]   [m_file_no: 0 m_page: 98 m_page_idx: 16 ]
4 rows returned
```

25.5.26 ndb_select_count — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

**Usage**

```
ndb_select_count [-c connection_string] -d db_name, tbl_name[, tbl_name2[,...]]
```

Options that can be used with `ndb_select_count` are shown in the following table. Additional descriptions follow the table.
• **--character-sets-dir**

  **Command-Line Format**

  --character-sets-dir=path

  Directory containing character sets.

• **--connect-retries**

  **Command-Line Format**

  --connect-retries=#

  **Type**
  Integer

  **Default Value**
  12

  **Minimum Value**
  0

  **Maximum Value**
  12

  Number of times to retry connection before giving up.

• **--connect-retry-delay**

  **Command-Line Format**

  --connect-retry-delay=#

  **Type**
  Integer

  **Default Value**
  5

  **Minimum Value**
  0

  **Maximum Value**
  5

  Number of seconds to wait between attempts to contact management server.

• **--connect-string**

  **Command-Line Format**

  --connect-string=connection_string

  **Type**
  String

  **Default Value**
  [none]

  Same as **--ndb-connectstring**.

• **--core-file**

  **Command-Line Format**

  --core-file

  Write core file on error; used in debugging.

• **--defaults-file**

  **Command-Line Format**

  --defaults-file=path

  **Type**
  String

  **Default Value**
  [none]

  Read default options from given file only.

• **--defaults-extra-file**

  **Command-Line Format**

  --defaults-extra-file=path

  **Type**
  String

  **Default Value**
  [none]
ndb_select_count — Print Row Counts for NDB Tables

Read given file after global files are read.

- **--defaults-group-suffix**
  
  **Command-Line Format**
  
  `--defaults-group-suffix=string`
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Also read groups with concat(group, suffix).

- **--login-path**
  
  **Command-Line Format**
  
  `--login-path=path`
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Read given path from login file.

- **--no-login-paths**
  
  **Command-Line Format**
  
  `--no-login-paths`
  
  Skips reading options from the login path file.

- **--help**
  
  **Command-Line Format**
  
  `--help`
  
  Display help text and exit.

- **--ndb-connectstring**
  
  **Command-Line Format**
  
  `--ndb-connectstring=connection_string`
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  

- **--ndb-mgm-tls**
  
  **Command-Line Format**
  
  `--ndb-mgm-tls=level`
  
  **Type**
  
  Enumeration
  
  **Default Value**
  
  relaxed
  
  **Valid Values**
  
  relaxed
  
  strict
  
  Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.
• **--ndb-mgmd-host**
  
  **Command-Line Format**  
  ```
  --ndb-mgmd-host=connection_string
  ```
  
  **Type**  
  String
  
  **Default Value**  
  [none]
  
  Same as **--ndb-connectstring**.

• **--ndb-nodeid**
  
  **Command-Line Format**  
  ```
  --ndb-nodeid=##
  ```
  
  **Type**  
  Integer
  
  **Default Value**  
  [none]
  
  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

• **--ndb-optimized-node-selection**
  
  **Command-Line Format**  
  ```
  --ndb-optimized-node-selection
  ```
  
  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

• **--ndb-tls-search-path**
  
  **Command-Line Format**  
  ```
  --ndb-tls-search-path=list
  ```
  
  **Type**  
  Path name
  
  **Default Value (Unix)**  
  $HOME/ndb-tls
  
  **Default Value (Windows)**  
  $HOMEDIR/ndb-tls
  
  Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

  Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

  If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using **-DWITH_NDB_TLS_SEARCH_PATH**.

• **--no-defaults**
  
  **Command-Line Format**  
  ```
  --no-defaults
  ```
  
  Do not read default options from any option file other than login file.

• **--print-defaults**
  
  **Command-Line Format**  
  ```
  --print-defaults
  ```
  
  Print program argument list and exit.

• **--usage**
ndb_show_tables — Display List of NDB Tables

Command-Line Format:  
```
--usage
```
Display help text and exit; same as `--help`.

- `--version`

Command-Line Format:  
```
--version
```
Display version information and exit.

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under Sample Output.

Sample Output

```
$> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
```

25.5.27 ndb_show_tables — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

Options that can be used with `ndb_show_tables` are shown in the following table. Additional descriptions follow the table.

Usage

```
ndb_show_tables [-c connection_string]
```

- `--character-sets-dir`

Command-Line Format:  
```
--character-sets-dir=path
```
Directory containing character sets.

- `--connect-retries`

Command-Line Format:  
```
--connect-retries=#
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>12</td>
<td>0</td>
<td>12</td>
</tr>
</tbody>
</table>

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format:  
```
--connect-retry-delay=#
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>5</td>
<td>0</td>
</tr>
</tbody>
</table>
ndb_show_tables — Display List of NDB Tables

Maximum Value

Number of seconds to wait between attempts to contact management server.

- **--connect-string**

  **Command-Line Format**
  
  --connect-string=connection_string

  **Type**
  String

  **Default Value**
  [none]

  Same as --ndb-connectstring.

- **--core-file**

  **Command-Line Format**
  
  --core-file

  Write core file on error; used in debugging.

- **--database, -d**

  Specifies the name of the database in which the desired table is found. If this option is given, the name of a table must follow the database name.

  If this option has not been specified, and no tables are found in the TEST_DB database, ndb_show_tables issues a warning.

- **--defaults-extra-file**

  **Command-Line Format**
  
  --defaults-extra-file=path

  **Type**
  String

  **Default Value**
  [none]

  Read given file after global files are read.

- **--defaults-file**

  **Command-Line Format**
  
  --defaults-file=path

  **Type**
  String

  **Default Value**
  [none]

  Read default options from given file only.

- **--defaults-group-suffix**

  **Command-Line Format**
  
  --defaults-group-suffix=string

  **Type**
  String

  **Default Value**
  [none]

  Also read groups with concat(group, suffix).

- **--help**

  **Command-Line Format**
  
  --help

  Display help text and exit.

- **--login-path**
ndb_show_tables — Display List of NDB Tables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--login-path=path</td>
<td>String</td>
<td>[none]</td>
<td>Read given path from login file.</td>
</tr>
</tbody>
</table>

- **--no-login-paths**

  Skips reading options from the login path file.

- **--loops, -l**

  Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- **--ndb-connectstring**

- **--ndb-mgm-tls**

  Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

- **--ndb-mgmd-host**

  Same as --ndb-connectstring.

- **--ndb-nodeid**

  Set node ID for this node, overriding any ID set by --ndb-connectstring.
--ndb-optimized-node-selection

Command-Line Format: --ndb-optimized-node-selection

Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

--ndb-tls-search-path

Command-Line Format: --ndb-tls-search-path=list

<table>
<thead>
<tr>
<th>Type</th>
<th>Path name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value (Unix)</td>
<td>$HOME/ndb-tls</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td>$HOMEDIR/ndb-tls</td>
</tr>
</tbody>
</table>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:) ; on Windows systems, the semicolon character (;;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls ; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using -DWITH_NDB_TLS_SEARCH_PATH.

--no-defaults

Command-Line Format: --no-defaults

Do not read default options from any option file other than login file.

--parsable, -p

Using this option causes the output to be in a format suitable for use with LOAD DATA.

--print-defaults

Command-Line Format: --print-defaults

Print program argument list and exit.

--show-temp-status

If specified, this causes temporary tables to be displayed.

--type, -t

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table
- 3: Unique hash index

Any other value causes all NDB database objects to be listed (the default).
25.5.28 ndb_sign_keys — Create, Sign, and Manage TLS Keys and Certificates for NDB Cluster

Management of TLS keys and certificates in implemented in NDB Cluster as the executable utility program `ndb_sign_keys`, which can normally be found in the MySQL bin directory. The program performs such functions as creating, signing, and retiring keys and certificates, and normally works as follows:

1. `ndb_sign_keys` connects to `ndb_mgmd` and fetches the cluster' configuration.
2. For each cluster node that is configured to run on the local machine, `ndb_sign_keys` finds the node' private key and sign it, creating an active node certificate.

Some additional tasks that can be performed by `ndb_sign_keys` are listed here:

- Obtaining configuration information from a config.ini file rather than a running `ndb_mgmd`
- Creating the cluster' certificate authority (CA) if it does not yet exist
- Creating private keys
- Saving keys and certificates as pending rather than active
- Signing the key for a single node as specified using command-line options described later in this section
- Requesting a CA located on a remote host to sign a local key

Options that can be used with `ndb_sign_keys` are shown in the following table. Additional descriptions follow the table.

```
<table>
<thead>
<tr>
<th>Option</th>
<th>Command-Line Format</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--bind-host</td>
<td>--bind-host=host</td>
<td>String</td>
<td>mgmd, api</td>
</tr>
</tbody>
</table>
```

Additional options that can be used with `ndb_sign_keys` include:

- `--unqualified, -u`
  If specified, this causes unqualified object names to be displayed.
- `--usage`
  Display help text and exit; same as `--help`.
- `--version`
  Display version information and exit.

---

**Note**

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysql`. However, you can examine the contents of system tables using NDB API applications such as `ndb_select_all` (see Section 25.5.25, “ndb_select_all — Print Rows from an NDB Table”).
Create a certificate bound to a hostname list of node types that should have certificate hostname bindings, from the set \( \text{mgmd,db,api} \).

- **--bound-hostname**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bound-hostname=hostname</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Create a certificate bound to the hostname passed to this option.

- **--CA-cert**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--CA-cert=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NDB-Cluster-cert</td>
</tr>
</tbody>
</table>

Use the name passed to this option for the CA Certificate file.

- **--CA-days**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--CA-days=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.4.1</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1461</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

Set the lifetime of the certificate to this many days. The default is equivalent to 4 years plus 1 day. \(-1\) means the certificate never expires.

This option was added in NDB 8.4.1.

- **--CA-key**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--CA-key=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NDB-Cluster-private-key</td>
</tr>
</tbody>
</table>

Use the name passed to this option for the CA private key file.

- **--CA-ordinal**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--CA-ordinal=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Valid Values</td>
<td>First</td>
</tr>
<tr>
<td></td>
<td>Second</td>
</tr>
</tbody>
</table>

Set the ordinal CA name; defaults to \text{First} for \text{--create-CA} and \text{Second} for \text{--rotate-CA}. The Common Name in the CA certificate is “MySQL NDB Cluster ordinal Certificate”, where \text{ordinal} is the ordinal name passed to this option.
• **--CA-search-path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--CA-search-path=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:) on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path is limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is $HOMEPATH\ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This default can be overridden by compiling NDB Cluster using --DWITH_NDB_TLS_SEARCH_PATH.

• **--CA-tool**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--CA-tool=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Designate an executable helper tool, including the path.

• **--check**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--check</th>
</tr>
</thead>
</table>

Check certificate expiry dates.

• **--config-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--config-file=file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled by</td>
<td>no-config</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Supply the path to the cluster configuration file (usually config.ini).

• **--connect-retries**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

Set the number of times that ndb_sign_keys attempts to connect to the cluster. If you use -1, the program keeps trying to connect until it succeeds or is forced to stop.

• **--connect-retry-delay**
Command-Line Format

--connect-retry-delay=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

Set the number of seconds after a failed connection attempt which ndb_sign_keys waits before trying again, up to the number of times determined by --connect-retries.

• **--create-CA**

Command-Line Format

--create-CA

Create the CA key and certificate.

• **--create-key**

Command-Line Format

--create-key

Create or replace private keys.

• **--curve**

Command-Line Format

--curve=name

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>P-256</td>
</tr>
</tbody>
</table>

Use the named curve for encrypting node keys.

• **--defaults-extra-file**

Command-Line Format

--defaults-extra-file=path

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read this option file after the global files are read.

• **--defaults-file**

Command-Line Format

--defaults-file=path

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read this option file only.

• **--defaults-group-suffix**

Command-Line Format

--defaults-group-suffix=string

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read not only the usual option groups, but also groups with the usual names and a suffix of string.

• **--duration**
### Command-Line Format

**--duration=#**

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-500000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>0</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

Set the lifetime of certificates or signing requests, in seconds.

**--help**

Print help text and exit.

**--keys-to-dir**

Specify output directory for private keys (only); for this purpose, it overrides any value set for **--to-dir**.

**--login-path**

Read this path from the login file.

**--ndb-connectstring**

Set the connection string to use for connecting to `ndb_mgmd`, using the syntax `[nodeid=id;] [host=]hostname[:port]`. If this option is set, it overrides the value set for `NDB_CONNECTSTRING` (if any), as well as any value set in a `my.cnf` file.

**--ndb-mgm-tls**

<table>
<thead>
<tr>
<th>Type</th>
<th>Enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>relaxed</td>
</tr>
<tr>
<td>Valid Values</td>
<td>relaxed</td>
</tr>
</tbody>
</table>
strict

Sets the level of TLS support required for the ndb_mgm client; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

- **--ndb-tls-search-path**

  **Command-Line Format**
  
  --ndb-tls-search-path=list

  **Type**
  
  Path name

  **Default Value (Unix)**
  
  $HOME/ndb-tls

  **Default Value (Windows)**
  
  $HOMEDIR/ndb-tls

  Specify a list of directories containing TLS keys and certificates.

  For syntax, see the description of the **--CA-search-path** option.

- **--no-config**

  **Command-Line Format**
  
  --no-config

  Do not obtain the cluster configuration; create a single certificate based on the options supplied (including defaults for those not specified).

- **--no-defaults**

  **Command-Line Format**
  
  --no-defaults

  Do not read default options from any option file other than the login file.

- **--no-login-paths**

  **Command-Line Format**
  
  --no-login-paths

  Do not read login paths from the login path file.

- **--passphrase**

  **Command-Line Format**
  
  --passphrase=phrase

  **Type**
  
  String

  **Default Value**
  
  [none]

  Specify a CA key pass phrase.

- **--node-id**

  **Command-Line Format**
  
  --node-id=#

  **Type**
  
  Integer

  **Default Value**
  
  0

  **Minimum Value**
  
  0

  **Maximum Value**
  
  255

  Create or sign a key for the node having the specified node ID.
ndb_sign_keys — Create, Sign, and Manage TLS Keys and Certificates for NDB Cluster

- **--node-type**

  **Command-Line Format**  
  --node-type=set

  **Type**  
  Set

  **Default Value**  
  mgmd,db,api

  Create or sign keys for the specified type or types from the set (mgmd,db,api).

- **--pending**

  **Command-Line Format**  
  --pending

  Save keys and certificates as pending, rather than active.

- **--print-defaults**

  **Command-Line Format**  
  --print-defaults

  Print the program argument list, then exit.

- **--promote**

  **Command-Line Format**  
  --promote

  Promote pending files to active, then exit.

- **--remote-CA-host**

  **Command-Line Format**  
  --remote-CA-host=hostname

  **Type**  
  String

  **Default Value**  
  [none]

  Specify the address or hostname of a remote CA host.

- **--remote-exec-path**

  **Command-Line Format**  
  --remote-exec-path

  **Type**  
  Path name

  **Default Value**  
  [none]

  Provide the full path to an executable on the remote CA host specified with **--remote-CA-host**.

- **--remote-openssl**

  **Command-Line Format**  
  --remote-openssl

  Use OpenSSL for signing of keys on the remote CA host specified with **--remote-CA-host**.

- **--replace-by**

  **Command-Line Format**  
  --replace-by=#

  **Type**  
  Integer

  **Default Value**  
  -10

  **Minimum Value**  
  -128
Suggest a certificate replacement date for periodic checks, as a number of days after the CA expiration date. Use a negative number to indicate days before expiration.

**--rotate-CA**

Command-Line Format: `--rotate-CA`

Replace an older CA with a newer one. The new CA can be created using OpenSSL, or you can allow `ndb_sign_keys` to create the new one, in which case the new CA is created with an intermediate CA certificate, signed by the old CA.

**--schedule**

Command-Line Format: `--schedule=list`

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>120,10,130,10,150,0</td>
</tr>
</tbody>
</table>

Assign a schedule of expiration dates to certificates. The schedule is defined as a comma-delimited list of six integers, in the format shown here:

```
api_valid,api_extra,dn_valid,dn_extra,mgm_valid,mgm_extra
```

These values are defined as follows:

- **api_valid**: A fixed number of days of validity for client certificates.
- **api_extra**: A number of extra days for client certificates.
- **dn_valid**: A fixed number of days of validity for client certificates for data node certificates.
- **dn_extra**: A number of extra days for data node certificates.
- **mgm_valid**: A fixed number of days of validity for management server certificates.
- **mgm_extra**: A number of extra days for management server certificates.

In other words, for each node type (API node, data node, management node), certificates are created with a lifetime equal to a whole fixed number of days, plus some random amount of time less than or equal to the number of extra days. The default schedule is shown here:

```
--schedule=120,10,130,10,150,0
```

Following the default schedule, client certificates begin expiring on the 120\textsuperscript{th} day, and expire at random intervals over the next 10 days; data node certificates expire at random times between the 130\textsuperscript{th} and 140\textsuperscript{th} days; and management node certificates expire on the 150\textsuperscript{th} day (with no random interval following).

**--sign**

Command-Line Format: `--sign`

Create signed certificates; enabled by default. Use `--skip-sign` to create certificate signing requests instead.

**--skip-sign**

Command-Line Format: `--skip-sign`
Create certificate signing requests instead of signed certificates.

- **--stdio**

Command-Line Format: **--stdio**

Read certificate signing requests from stdin, and write X.509 to stdout.

- **--to-dir**

Command-Line Format: **--to-dir=dirname**

Type: Directory name

Default Value: [none]

Specify the output directory for created files. For private key files, this can be overridden using **--keys-to-dir**.

- **--usage**

Command-Line Format: **--usage**

Print help text, then exit (alias for **--help**).

- **--version**

Command-Line Format: **--version**

Print version information, then exit.

### 25.5.29 ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

#### Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.
- A working installation of Perl.
- The DBI module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using GRANT USAGE ON db_name.*—where db_name is the name of the database to be examined—is sufficient for this purpose.

ndb_size.pl can also be found in the MySQL sources in storage/ndb/tools.

Options that can be used with ndb_size.pl are shown in the following table. Additional descriptions follow the table.

#### Usage

```bash
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] 
```
By default, this utility attempts to analyze all databases on the server. You can specify a single database using the --database option; the default behavior can be made explicit by using ALL for the name of the database. You can also exclude one or more databases by using the --excludedbs option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional --excludetables option. A host name can be specified using --hostname; the default is localhost. You can specify a port in addition to the host using host:port format for the value of --hostname. The default port number is 3306. If necessary, you can also specify a socket; the default is /var/lib/mysql.sock. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the --format option; this can take either of the values html or text, with text being the default. An example of the text output is shown here:

```
$> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
-------------------
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock
Including information for versions: 4.1, 5.0, 5.1

<td>5</td>
<td>5</td>
<td>5</td>
</tr>
</tbody>
</table>
```

* indicates greater than default

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
$> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the DataMemory, IndexMemory, MaxNoOfTables, MaxNoOfAttributes, MaxNoOfOrderedIndexes, and MaxNoOfTriggers configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The IndexMemory and DataMemory required per table and table row.

## 25.5.30 ndb_top — View CPU usage information for NDB threads

**ndb_top** displays running information in the terminal about CPU usage by NDB threads on an NDB Cluster data node. Each thread is represented by two rows in the output, the first showing system statistics, the second showing the measured statistics for the thread.

**ndb_top** is available beginning with MySQL NDB Cluster 7.6.3.

### Usage

```
ndb_top [-h hostname] [-t port] [-u user] [-p pass] [-n node_id]
```

**ndb_top** connects to a MySQL Server running as an SQL node of the cluster. By default, it attempts to connect to a `mysqld` running on `localhost` and port 3306, as the MySQL `root` user with no password specified. You can override the default host and port using, respectively, `--host (-h)` and `--port (-t)`. To specify a MySQL user and password, use the `--user (-u)` and `--passwd (-p)` options. This user must be able to read tables in the `ndbinfo` database (**ndb_top** uses information from `ndbinfo.cpustat` and related tables).

For more information about MySQL user accounts and passwords, see Section 8.2, “Access Control and Account Management”.

Output is available as plain text or an ASCII graph; you can specify this using the `--text (-x)` and `--graph (-g)` options, respectively. These two display modes provide the same information; they can be used concurrently. At least one display mode must be in use.
Color display of the graph is supported and enabled by default (\texttt{--color} or \texttt{-c} option). With color support enabled, the graph display shows OS user time in blue, OS system time in green, and idle time as blank. For measured load, blue is used for execution time, yellow for send time, red for time spent in send buffer full waits, and blank spaces for idle time. The percentage shown in the graph display is the sum of percentages for all threads which are not idle. Colors are not currently configurable; you can use grayscale instead by using \texttt{--skip-color}.

The sorted view (\texttt{--sort}, \texttt{-r}) is based on the maximum of the measured load and the load reported by the OS. Display of these can be enabled and disabled using the \texttt{--measured-load} (\texttt{-m}) and \texttt{--os-load} (\texttt{-o}) options. Display of at least one of these loads must be enabled.

The program tries to obtain statistics from a data node having the node ID given by the \texttt{--node-id} (\texttt{-n}) option; if unspecified, this is 1. \texttt{ndb_top} cannot provide information about other types of nodes.

The view adjusts itself to the height and width of the terminal window; the minimum supported width is 76 characters.

Once started, \texttt{ndb_top} runs continuously until forced to exit; you can quit the program using Ctrl-C. The display updates once per second; to set a different delay interval, use \texttt{--sleep-time} (\texttt{-s}).

\textbf{Note}

\texttt{ndb_top} is available on macOS, Linux, and Solaris. It is not currently supported on Windows platforms.

The following table includes all options that are specific to the NDB Cluster program \texttt{ndb_top}. Additional descriptions follow the table.

### Additional Options

- \texttt{--color}, \texttt{-c}

\textbf{Command-Line Format}

\texttt{--color}

\textbf{Show ASCII graphs in color; use \texttt{--skip-colors} to disable.}

- \texttt{--defaults-extra-file}

\textbf{Command-Line Format}

\texttt{--defaults-extra-file=path}

\textbf{Type}

String

\textbf{Default Value}

[none]

Read given file after global files are read.

- \texttt{--defaults-file}

\textbf{Command-Line Format}

\texttt{--defaults-file=path}

\textbf{Type}

String

\textbf{Default Value}

[none]

Read default options from given file only.

- \texttt{--defaults-group-suffix}

\textbf{Command-Line Format}

\texttt{--defaults-group-suffix=string}

\textbf{Type}

String

\textbf{4211}
<table>
<thead>
<tr>
<th>Default Value</th>
<th>[none]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Also read groups with concat(group, suffix).</td>
<td></td>
</tr>
</tbody>
</table>

- **--graph, -g**

  **Command-Line Format**
  
  `--graph`

  Display data using graphs; use **--skip-graphs** to disable. This option or **--text** must be true; both options may be true.

- **--help, -?**

  **Command-Line Format**
  
  `--help`

  Show program usage information.

- **--host[^=name], -h**

  **Command-Line Format**
  
  `--host=string`

  **Type**
  
  String

  **Default Value**
  
  `localhost`

  Host name or IP address of MySQL Server to connect to.

- **--login-path**

  **Command-Line Format**
  
  `--login-path=path`

  **Type**
  
  String

  **Default Value**
  
  [none]

  Read given path from login file.

- **--no-login-paths**

  **Command-Line Format**
  
  `--no-login-paths`

  Skips reading options from the login path file.

- **--measured-load, -m**

  **Command-Line Format**
  
  `--measured-load`

  Show measured load by thread. This option or **--os-load** must be true; both options may be true.

- **--no-defaults**

  **Command-Line Format**
  
  `--no-defaults`

  Do not read default options from any option file other than login file.

- **--node-id[^=#], -n**

  **Command-Line Format**
  
  `--node-id=#`

  **Type**
  
  Integer

  **Default Value**
  
  1

  Watch the data node having this node ID.
- **--os-load, --os-load**
  
  **Command-Line Format**  
  ```
  --os-load
  ```
  
  Show load measured by operating system. This option or **--measured-load** must be true; both options may be true.

- **--password=[password], -p**
  
  **Command-Line Format**  
  ```
  --password=password
  ```
  
  **Type**  
  String

  **Default Value**  
  NULL

  Connect to a MySQL Server using this password and the MySQL user specified by **--user**. This password is associated with a MySQL user account only, and is not related in any way to the password used with encrypted NDB backups.

- **--port=[#], -P**
  
  **Command-Line Format**  
  ```
  --port=#
  ```
  
  **Type**  
  Integer

  **Default Value**  
  3306

  Port number to use when connecting to MySQL Server.

  (Formerly, the short form for this option was `-t`, which was repurposed as the short form of **--text**.)

- **--print-defaults**
  
  **Command-Line Format**  
  ```
  --print-defaults
  ```

  Print program argument list and exit.

- **--sleep-time=[seconds], -s**
  
  **Command-Line Format**  
  ```
  --sleep-time=#
  ```
  
  **Type**  
  Integer

  **Default Value**  
  1

  Time to wait between display refreshes, in seconds.

- **--socket==path/to/file, -S**
  
  **Command-Line Format**  
  ```
  --socket=path
  ```
  
  **Type**  
  Path name

  **Default Value**  
  [none]

  Use the specified socket file for the connection.

- **--sort, -r**
  
  **Command-Line Format**  
  ```
  --sort
  ```

  Sort threads by usage; use **--skip-sort** to disable.

- **--text, -t**
ndb_top — View CPU usage information for NDB threads

**Command-Line Format**

--text

Display data using text. This option or --graph must be true; both options may be true.

(The short form for this option was -x in previous versions of NDB Cluster, but this is no longer supported.)

**--usage**

Command-Line Format

--usage

Display help text and exit; same as --help.

**--user=[name], -u**

Command-Line Format

--user=name

Type

String

Default Value

root

Connect as this MySQL user. Normally requires a password supplied by the --password option.

**Sample Output.** The next figure shows ndb_top running in a terminal window on a Linux system with an ndbmttd data node under a moderate load. Here, the program has been invoked using ndb_top -n 8 -x to provide both text and graph output:
ndb_waiter — Wait for NDB Cluster to Reach a Given Status

ndb_waiter repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the --timeout limit is exceeded, then exits. By default, it waits for the cluster to achieve STARTED status, in which all nodes have started and connected to the cluster. This can be overridden using the --no-contact and --not-started options.

The node states reported by this utility are as follows:

- **NO_CONTACT**: The node cannot be contacted.
- **UNKNOWN**: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a START or RESTART command from the management server, but has not yet acted on it.
- **NOT_STARTED**: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's RESTART command.
- **STARTING**: The node's ndbd process has started, but the node has not yet joined the cluster.
- **STARTED**: The node is operational, and has joined the cluster.
- **SHUTTING_DOWN**: The node is shutting down.

**ndb_top** also shows spin times for threads, displayed in green.

Figure 25.5 ndb_top Running in Terminal
• **SINGLE USER MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

Options that can be used with `ndb_waiter` are shown in the following table. Additional descriptions follow the table.

### Usage

```
ndb_waiter [-c connection_string]
```

### Additional Options

- **--character-sets-dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-sets-dir=path</th>
</tr>
</thead>
</table>

Directory containing character sets.

- **--connect-retries**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

Number of times to retry connection before giving up.

- **--connect-retry-delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retry-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

- **--connect-string**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-string=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as `--ndb-connectstring`.

- **--core-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--core-file</th>
</tr>
</thead>
</table>

Write core file on error; used in debugging.

- **--defaults-extra-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-extra-file=path</th>
</tr>

**Type**

- **String**

**Default Value**

- [none]

---

**Read given file after global files are read.**

- **--defaults-file**

  **Command-Line Format**

  `--defaults-file=path`

  **Type**

  - **String**

  **Default Value**

  - [none]

---

**Read default options from given file only.**

- **--defaults-group-suffix**

  **Command-Line Format**

  `--defaults-group-suffix=string`

  **Type**

  - **String**

  **Default Value**

  - [none]

---

**Also read groups with concat(group, suffix).**

- **--login-path**

  **Command-Line Format**

  `--login-path=path`

  **Type**

  - **String**

  **Default Value**

  - [none]

---

**Read given path from login file.**

- **--no-login-paths**

  **Command-Line Format**

  `--no-login-paths`

---

**Skips reading options from the login path file.**

- **--help**

  **Command-Line Format**

  `--help`

---

**Display help text and exit.**

- **--ndb-connectstring**

  **Command-Line Format**

  `--ndb-connectstring=connection_string`

  **Type**

  - **String**

  **Default Value**

  - [none]

---

**Set connection string for connecting to ndb_mgmd. Syntax: [nodeid=id;] [host=]hostname[:port]. Overrides entries in NDB_CONNECTSTRING and my.cnf.**

- **--ndb-mgm-tls**

  **Command-Line Format**

  `--ndb-mgm-tls=level`

  **Type**

  - **Enumeration**
ndb_waiter — Wait for NDB Cluster to Reach a Given Status

Sets the level of TLS support required to connect to the management server; one of relaxed or strict. relaxed (the default) means that a TLS connection is attempted, but success is not required; strict means that TLS is required to connect.

- --ndb-mgmd-host
  Command-Line Format: --ndb-mgmd-host=connection_string
  Type: String
  Default Value: [none]
  Same as --ndb-connectstring.

- --ndb-nodeid
  Command-Line Format: --ndb-nodeid=#
  Type: Integer
  Default Value: [none]
  Set node ID for this node, overriding any ID set by --ndb-connectstring.

- --ndb-optimized-node-selection
  Command-Line Format: --ndb-optimized-node-selection
  Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

- --ndb-tls-search-path
  Command-Line Format: --ndb-tls-search-path=list
  Type: Path name
  Default Value (Unix): $HOME/ndb-tls
  Default Value (Windows): $HOMEDIR/ndb-tls
  Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign ($), and expanded prior to use. Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.
  If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is \ndb-tls; on other platforms (including Linux), it is $HOME/ndb-tls. This can be overridden by compiling NDB Cluster using -DWITH_NDB_TLS_SEARCH_PATH.

- --no-contact, -n
  Instead of waiting for the STARTED state, ndb_waiter continues running until the cluster reaches NO_CONTACT status before exiting.
ndb_waiter — Wait for NDB Cluster to Reach a Given Status

• **--no-defaults**

  Command-Line Format: `--no-defaults`

  Do not read default options from any option file other than login file.

• **--not-started**

  Instead of waiting for the STARTED state, ndb_waiter continues running until the cluster reaches NOT_STARTED status before exiting.

• **--nowait-nodes=list**

  When this option is used, ndb_waiter does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```
  $> ndb_waiter --nowait-nodes=1,3,7-9
  ```

  **Important**
  Do not use this option together with the --wait-nodes option.

• **--print-defaults**

  Command-Line Format: `--print-defaults`

  Print program argument list and exit.

• **--timeout=seconds, -t seconds**

  Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

• **--single-user**

  The program waits for the cluster to enter single user mode.

• **--usage**

  Command-Line Format: `--usage`

  Display help text and exit; same as `--help`.

• **--verbose**

  Command-Line Format: `--verbose=##`

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2</td>
</tr>
</tbody>
</table>

  Controls verbosity level of printout. Possible levels and their effects are listed here:

  • **0**: Do not print (return exit code only; see following for exit codes).
  • **1**: Print final connection status only.
  • **2**: Print status each time it is checked.

  This is the same behavior as in versions of NDB Cluster previous to 8.4.
Exit codes returned by `ndb_waiter` are listed here, with their meanings:

- **0**: Success.
- **1**: Wait timed out.
- **2**: Parameter error, such as an invalid node ID.
- **3**: Failed to connect to the management server.
- **--version**

Display version information and exit.

- **--wait-nodes=list,-w list**

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
$> ndb_waiter --wait-nodes=2,4-6,10
```

Important

Do not use this option together with the `--nowait-nodes` option.

Sample Output. Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by ...) are omitted.

```
$> ./ndb_waiter -c localhost
Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED

Note
If no connection string is specified, then ndb_waiter tries to connect to a management on localhost, and reports Connecting to mgmsrv at (null).

25.5.32 ndbxfrm — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster

The ndbxfrm utility can be used to decompress, decrypt, and output information about files created by NDB Cluster that are compressed, encrypted, or both. It can also be used to compress or encrypt files.

Usage

ndbxfrm --info file[ file ...]
ndbxfrm --compress input_file output_file
ndbxfrm --decrypt-password=password input_file output_file
ndbxfrm [--encrypt-ldf-iter-count=#] --encrypt-password=password input_file output_file

input_file and output_file cannot be the same file.

Options

- **--compress, -c**

  Command-Line Format
  
<table>
<thead>
<tr>
<th>--compress</th>
</tr>
</thead>
</table>

  Compresses the input file, using the same compression method as is used for compressing NDB Cluster backups, and writes the output to an output file. To decompress a compressed NDB backup file that is not encrypted, it is necessary only to invoke ndbxfrm using the names of the compressed file and an output file (with no options required).

- **--decrypt-key=key, -K key**

  Command-Line Format
  
<table>
<thead>
<tr>
<th>--decrypt-key=key</th>
</tr>
</thead>
</table>

  Decrypts a file encrypted by NDB using the supplied key.
Note
This option cannot be used together with --decrypt-password.

• --decrypt-key-from-stdin

Command-Line Format
--decrypt-key-from-stdin

Decrypts a file encrypted by NDB using the key supplied from stdin.

• --decrypt-password=password

Command-Line Format
--decrypt-password=password

Type
String

Default Value
[none]

Decrypts a file encrypted by NDB using the password supplied.

Note
This option cannot be used together with --decrypt-key.

• --decrypt-password-from-stdin[=TRUE|FALSE]

Command-Line Format
--decrypt-password-from-stdin

Decrypts a file encrypted by NDB, using a password supplied from standard input. This is similar to entering a password after invoking mysql --password with no password following the option.

• --defaults-extra-file

Command-Line Format
--defaults-extra-file=path

Type
String

Default Value
[none]

Read given file after global files are read.

• --defaults-file

Command-Line Format
--defaults-file=path

Type
String

Default Value
[none]

Read default options from given file only.

• --defaults-group-suffix

Command-Line Format
--defaults-group-suffix=string

Type
String

Default Value
[none]

Also read groups with CONCAT(group, suffix).
**--detailed-info**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--encrypt-block-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Print out file information like `--info`, but include the file's header and trailer.

**Example:**

```
$> ndbxfrm --detailed-info S0.sysfile
File=/var/lib/cluster-data/ndb_7_fs/01/NDBCNTR/S0.sysfile, compression=no, encryption=yes
header: {

<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

Cipher used for encryption. Set to 1 for CBC mode (the default), or 2 for XTS.

• **--encrypt-kdf-iter-count=#, -k #**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--encrypt-kdf-iter-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

When encrypting a file, specifies the number of iterations to use for the encryption key. Requires the --encrypt-password option.

• **--encrypt-key=key**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--encrypt-key=key</th>
</tr>
</thead>
</table>

Encrypts a file using the supplied key.

**Note**

This option cannot be used together with --encrypt-password.

• **--encrypt-key-from-stdin**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--encrypt-key-from-stdin</th>
</tr>
</thead>
</table>

Encrypt a file using the key supplied from stdin.

• **--encrypt-password=password**
ndbxfm — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster

### Command-Line Format

---

**--encrypt-password=password**

**Type**: String  
**Default Value**: [none]

Encrypts the backup file using the password supplied by the option. The password must meet the requirements listed here:

- Uses any of the printable ASCII characters except !, ', "", $, %, \\, `, and ^
- Is no more than 256 characters in length
- Is enclosed by single or double quotation marks

**Note**

This option cannot be used together with `--encrypt-key`.

---

**--encrypt-password-from-stdin**

**Command-Line Format**: --encrypt-password-from-stdin

Encrypts a file using a password supplied from standard input. This is similar to entering a password entered after invoking `mysql --password` with no password following the option.

---

**--help**

**Command-Line Format**: --help

Prints usage information for the program.

---

**--info**

**Command-Line Format**: --info

Prints the following information about one or more input files:

- The name of the file
- Whether the file is compressed (compression=yes or compression=no)
- Whether the file is encrypted (encryption=yes or encryption=no)

**Example**:

```shell
$> ndbxfm -i BACKUP-10-0.5.Data BACKUP-10.5.ctl BACKUP-10.5.log
File=BACKUP-10-0.5.Data, compression=no, encryption=yes
File=BACKUP-10.5.ctl, compression=no, encryption=yes
File=BACKUP-10.5.log, compression=no, encryption=yes
```

You can also see the file's header and trailer using the `--detailed-info` option.

---

**--login-path**

**Command-Line Format**: --login-path=path

**Type**: String  
**Default Value**: [none]

Read given path from login file.
Management of NDB Cluster

- **--no-login-paths**

  Command-Line Format
  
  --no-login-paths

  Skips reading options from the login path file.

- **--no-defaults**

  Command-Line Format
  
  --no-defaults

  Do not read default options from any option file other than login file.

- **--print-defaults**

  Command-Line Format
  
  --print-defaults

  Print program argument list and exit.

- **--usage, -?**

  Command-Line Format
  
  --usage

  Synonym for **--help**.

- **--version, -V**

  Command-Line Format
  
  --version

  Prints out version information.

`ndbxfrm` can encrypt backups created by any version of NDB Cluster. The `.Data`, `.ctl`, and `.log` files comprising the backup must be encrypted separately, and these files must be encrypted separately for each data node. Once encrypted, such backups can be decrypted only by `ndbxfrm`, `ndb_restore`, or `ndb_print_backup`.

An encrypted file can be re-encrypted with a new password using the **--encrypt-password** and **--decrypt-password** options together, like this:

```
ndbxfrm --decrypt-password=old --encrypt-password=new input_file output_file
```

In the example just shown, `old` and `new` are the old and new passwords, respectively; both of these must be quoted. The input file is decrypted and then encrypted as the output file. The input file itself is not changed; if you do not want it to be accessible using the old password, you must remove the input file manually.

### 25.6 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in Section 25.4, “Configuration of NDB Cluster”, and Section 25.5, “NDB Cluster Programs”.

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see Section 25.6.21, “NDB Cluster Security Issues”.

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The
second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's DataDir directory, but this location can be overridden using the LogDestination option. (Recall that node_id represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by ndbd. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the SHOW ENGINE NDB STATUS statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the ndbinfo database. For more information, see Section 25.6.17, "ndbinfo: The NDB Cluster Information Database".

NDB statistics counters provide improved monitoring using the mysql client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting Ndb objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

dbd exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (Ndb_api__). The values of these variables can be read in the mysql client from the output of a SHOW STATUS statement, or by querying either the Performance Schema session_status or global_status table. By comparing the values of the status variables before and after the execution of an SQL statement that acts on NDB tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as mysql server options and variables relating to NDB Cluster. See MySQL Cluster Manager 8.4.1 User Manual, for more information.

### 25.6.1 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client ndb_mgm. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 25.6.3, “Event Reports Generated in NDB Cluster”; commands for creating backups and restoring from them are provided in Section 25.6.8, “Online Backup of NDB Cluster”.

**Using ndb_mgm with MySQL Cluster Manager.** MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use ndb_mgm for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended not to use the ndb_mgm command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the START, STOP, RESTART, and SHUTDOWN commands. For more information, see MySQL Cluster Manager Process Commands.

The management client has the following basic commands. In the listing that follows, node_id denotes either a data node ID or the keyword ALL, which indicates that the command should be applied to all of the cluster's data nodes.

- **CONNECT connection-string**
Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- **CREATE NODEGROUP nodeid[, nodeid, ...]**

Creates a new NDB Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started, and that are to join the new node group. The list must contain no duplicate IDs; the presence of any duplicates causes the command to return an error. The number of nodes in the list must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster consists of 2 node groups having 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

For more information, see Section 25.6.7, “Adding NDB Cluster Data Nodes Online”.

- **DROP NODEGROUP nodegroup_id**

Drops the NDB Cluster node group with the given nodegroup_id.

This command can be used to drop a node group from an NDB Cluster. DROP NODEGROUP takes as its sole argument the node group ID of the node group to be dropped.

DROP NODEGROUP acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client SHOW command with no nodegroup in place of the node group ID, like this (indicated using bold text):

```plaintext
id=3    @10.100.2.67  (8.4.0-ndb-8.4.0, no nodegroup)
```

DROP NODEGROUP works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using ndb_mgm or the mysql client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing CREATE NODEGROUP in the ndb_mgm client, but before issuing any ALTER TABLE ... REORGANIZE PARTITION statements in the mysql client.

2. After dropping all NDBCLUSTER tables using DROP TABLE.

   TRUNCATE TABLE does not work for this purpose because this removes only the table data; the data nodes continue to store an NDBCLUSTER table's definition until a DROP TABLE statement is issued that causes the table metadata to be dropped.

For more information about DROP NODEGROUP, see Section 25.6.7, “Adding NDB Cluster Data Nodes Online”.

- **ENTER SINGLE USER MODE node_id**

Enters single user mode, whereby only the MySQL server identified by the node ID node_id is permitted to access the database.

The ndb_mgm client provides a clear acknowledgement that this command has been issued and has taken effect, as shown here:
In addition, the API or SQL node having exclusive access when in single user mode is indicated in the output of the `SHOW` command, like this:

```
ndb_mgm> SHOW
Cluster Configuration
----------------------
[ndbd(NDB)]     2 node(s)
id=5    @127.0.0.1 (mysql-8.4.0 ndb-8.4.0, single user mode, Nodegroup: 0, *)
id=6    @127.0.0.1 (mysql-8.4.0 ndb-8.4.0, single user mode, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=50   @127.0.0.1 (mysql-8.4.0 ndb-8.4.0)

[mysqld(API)]   2 node(s)
id=100  @127.0.0.1 (mysql-8.4.0 ndb-8.4.0, allowed single user)
id=101 (not connected, accepting connect from any host)
```

• **EXIT SINGLE USER MODE**

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

Note

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

• **HELP**

Displays information on all available commands.

• **node_id NODELOG DEBUG {ON|OFF}**

Toggles debug logging in the node log, as though the effected data node or nodes had been started with the `--verbose` option. `NODELOG DEBUG ON` starts debug logging; `NODELOG DEBUG OFF` switches debug logging off.

• **PROMPT [prompt]**

Changes the prompt shown by `ndb_mgm` to the string literal `prompt`.

`prompt` should not be quoted (unless you want the prompt to include the quotation marks). Unlike the case with the `mysql` client, special character sequences and escapes are not recognized. If called without an argument, the command resets the prompt to the default value (`ndb_mgm>`).

Some examples are shown here:

```
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration
...
mgm#1: PROMPT mymgm >
mymgm > PROMPT 'mymgm: '
'mymgm:' PROMPT mymgm:
mymgm: PROMPT
ndb_mgm> EXIT
$>
```

Note that leading spaces and spaces within the `prompt` string are not trimmed. Trailing spaces are removed.

• **QUIT,EXIT**
Terminates the management client.

This command does not affect any nodes connected to the cluster.

- **node_id REPORT report-type**

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are three accepted values for `report-type`:

- **BackupStatus** provides a status report on a cluster backup in progress
- **MemoryUsage** displays how much data memory and index memory is being used by each data node as shown in this example:

  ```
  ndb_mgm> ALL REPORT MEMORY
  Node 1: Data usage is 5% (177 32K pages of total 3200)
  Node 1: Index usage is 0% (108 8K pages of total 12832)
  Node 2: Data usage is 5% (177 32K pages of total 3200)
  Node 2: Index usage is 0% (108 8K pages of total 12832)
  
  This information is also available from the `ndbinfo.memoryusage` table.
  ```
- **EventLog** reports events from the event log buffers of one or more data nodes.

  `report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- **node_id RESTART [-n] [-i] [-a] [-f]**

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

```
 Note
 Backup files and Disk Data files are not removed when this option is used.
```

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- **SHOW**

Displays basic information about the cluster and cluster nodes. For all nodes, the output includes the node's ID, type, and NDB software version. If the node is connected, its IP address is also shown;
otherwise the output shows not connected, accepting connect from ip_address, with any host used for nodes that are permitted to connect from any address.

In addition, for data nodes, the output includes starting if the node has not yet started, and shows the node group of which the node is a member. If the data node is acting as the master node, this is indicated with an asterisk (*).

Consider a cluster whose configuration file includes the information shown here (possible additional settings are omitted for clarity):

```
[ndbd default]
DataMemory= 128G
NoOfReplicas= 2

[ndb_mgmd]
NodeId=50
HostName=198.51.100.150

[ndbd]
NodeId=5
HostName=198.51.100.10
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=6
HostName=198.51.100.20
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=7
HostName=198.51.100.30
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=8
HostName=198.51.100.40
DataDir=/var/lib/mysql-cluster

[mysqld]
NodeId=100
HostName=198.51.100.100

[api]
NodeId=101
```

After this cluster (including one SQL node) has been started, `SHOW` displays the following output:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186 (using cleartext)
Cluster Configuration
---------------------
[ndbd(NDB)]     4 node(s)
id=5    @198.51.100.10  (mysql-8.4.0 ndb-8.4.0, Nodegroup: 0, *)
id=6    @198.51.100.20  (mysql-8.4.0 ndb-8.4.0, Nodegroup: 0)
id=7    @198.51.100.30  (mysql-8.4.0 ndb-8.4.0, Nodegroup: 1)
id=8    @198.51.100.40  (mysql-8.4.0 ndb-8.4.0, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=50   @198.51.100.150  (mysql-8.4.0 ndb-8.4.0)

[mysqld(API)]   2 node(s)
id=100  @198.51.100.100  (mysql-8.4.0 ndb-8.4.0)
id=101  (not connected, accepting connect from any host)
```

The output from this command also indicates when the cluster is in single user mode (see the description of the `ENTER SINGLE USER MODE` command, as well as Section 25.6.6, "NDB Cluster Single User Mode"). It also indicates which API or SQL node has exclusive access when this mode is in effect.
Commands in the NDB Cluster Management Client

• **SHUTDOWN**
  Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use **EXIT** or **QUIT**.
  This command does **not** shut down any SQL nodes or API nodes that are connected to the cluster.

• **node_id START**
  Brings online the data node identified by **node_id** (or all data nodes).
  **ALL START** works on all data nodes only, and does not affect management nodes.

  **Important**
  To use this command to bring a data node online, the data node must have been started using **--nostart** or **-n**.

• **node_id STATUS**
  Displays status information for the data node identified by **node_id** (or for all data nodes).
  Possible node status values include **UNKNOWN**, **NO_CONTACT**, **NOT_STARTED**, **STARTING**, **STARTED**, **SHUTTING_DOWN**, and **RESTARTING**.
  The output from this command also indicates when the cluster is in single user mode.

• **node_id STOP** [-a] [-f]
  Stops the data or management node identified by **node_id**.

  **Note**
  **ALL STOP** works to stop all data nodes only, and does not affect management nodes.

  A node affected by this command disconnects from the cluster, and its associated **ndbd** or **ndb_mgmd** process terminates.

  The **-a** option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

  Normally, **STOP** fails if the result would cause an incomplete cluster. The **-f** option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

  **Warning**
  Use of the **-a** option also disables the safety check otherwise performed when **STOP** is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the **-a** option with the **STOP** command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in **NDB**.

• **TLS INFO**
  Displays cluster TLS information such as whether the current connection is using TLS, TLS certificates currently known to the management node, and the management node’s counts of total connections, connections upgraded to TLS, and authorization failures. Sample output is shown here:
NDB Cluster Log Messages

For more information, see Section 25.6.15, "TLS Link Encryption for NDB Cluster".

Additional commands. A number of other commands available in the ndb_mgm client are described elsewhere, as shown in the following list:

- **START BACKUP** is used to perform an online backup in the ndb_mgm client; the **ABORT BACKUP** command is used to cancel a backup already in progress. For more information, see Section 25.6.8, "Online Backup of NDB Cluster".

- The **CLUSTERLOG** command is used to perform various logging functions. See Section 25.6.3, “Event Reports Generated in NDB Cluster”, for more information and examples. **NODELOG DEBUG** activates or deactivates debug printouts in node logs, as described previously in this section.

- For testing and diagnostics work, the client supports a **DUMP** command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see NDB Cluster Management Client DUMP Commands.

25.6.2 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on NDB transporter errors.

25.6.2.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common NDB cluster log messages. For information about the cluster log, log events, and event types, see Section 25.6.3, “Event Reports Generated in NDB Cluster”. These log messages also correspond to log event types in the MGM API; see The Ndb_logevent_type Type, for related information of interest to Cluster API developers.

<table>

</tbody>
</table>

This message reports on the result of arbitration. In the event of arbitration failure, an error_message and an arbitration state_code are provided; definitions for both of these are found in include/kernel/signaldata/ArbitSignalData.hpp.

ArbitResult check lost - less than 1/2 nodes left or Arbitration check lost - missing node group or Network partitioning - arbitration required or Arbitration lost - negative reply from node node_id or Arbitration lost - no arbitrator available or Network partitioning - no arbitrator

25.6.2.2 NDB Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting until nodes: %s connects, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting %u sec for nodes %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]
- Waiting %u sec for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]
- Initial start with nodes %s [ missing: %s no-wait: %s ]
- Start with all nodes %s
- Start with nodes %s [ missing: %s no-wait: %s ]
- Start potentially partitioned with nodes %s [ missing: %s no-wait: %s ]
- Unknown startreport: 0x%llx [ %s %s %s %s ]
25.6.2.3 Event Buffer Reporting in the Cluster Log

**NDB** uses one or more memory buffers for events received from the data nodes. There is one such buffer for each **Ndb** object subscribing to table events, which means that there are usually two buffers for each **mysqld** performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

**NDB** generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes).

Event buffer logging reports in the cluster log use the format shown here:

```
Node node_id: Event buffer status (object_id):
  used=bytes_used (percent_used% of alloc)
  alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
  latest_consumed_epoch=latest_consumed_epoch
  latest_buffered_epoch=latest_buffered_epoch
  report_reason=report_reason
```

The fields making up this report are listed here, with descriptions:

- **node_id**: ID of the node where the report originated.
- **object_id**: ID of the **Ndb** object where the report originated.
- **bytes_used**: Number of bytes used by the buffer.
- **percent_used**: Percentage of allocated bytes used.
- **bytes_allocated**: Number of bytes allocated to this buffer.
- **percent_allocated**: Percentage of available bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- **bytes_available**: Number of bytes available; this is 0 if `ndb_eventbuffer_max_alloc` is 0 (unlimited).
- **latest_consumed_epoch**: The epoch most recently consumed to completion. (In NDB API applications, this is done by calling `nextEvent()`)
- **latest_buffered_epoch**: The epoch most recently buffered (completely) in the event buffer.
- **report_reason**: The reason for making the report. Possible reasons are shown later in this section.

Possible reasons for reporting are described in the following list:

- **ENOUGH_FREE_EVENTBUFFER**: The event buffer has sufficient space.
- **LOW_FREE_EVENTBUFFER**: The event buffer is running low on free space.

The threshold free percentage level triggering these reports can be adjusted by setting the `ndb_report_thresh_binlog_mem_usage` server variable.

- **BUFFERED_EPOCHS_OVER_THRESHOLD**: Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.
- **PARTIALLY_DISCARDING**: Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even if usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.

- **COMPLETELY_DISCARDING**: No epochs are buffered.

- **PARTIALLY_BUFFERING**: The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.

- **COMPLETELY_BUFFERING**: All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

### 25.6.2.4 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Name</th>
<th>Message</th>
</tr>

0x16   TE_SEND_BUFFER_FULL
The send buffer was full, but sleeping for a while solved
0x21   TE_SHM_IPC_PERMANENT
Shm ipc Permanent error

Note
Transporter error codes 0x17 through 0x20 and 0x22 are reserved for SCI connections, which are not supported in this version of NDB Cluster, and so are not included here.

25.6.3 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The cluster log, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.
Event Reports Generated in NDB Cluster

By default, the cluster log is saved to a file named ndb_node_id_cluster.log, (where node_id is the node ID of the management server) in the management server's DataDir.

Cluster logging information can also be sent to stdout or a syslog facility in addition to or instead of being saved to a file, as determined by the values set for the DataDir and LogDestination configuration parameters. See Section 25.4.3.5, “Defining an NDB Cluster Management Server”, for more information about these parameters.

- **Node logs** are local to each node.

  Output generated by node event logging is written to the file ndb_node_id_out.log (where node_id is the node's node ID) in the node's DataDir. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Each reportable event can be distinguished according to three different criteria:

- **Category**: This can be any one of the following values: STARTUP, SHUTDOWN, STATISTICS, CHECKPOINT, NODERESTART, CONNECTION, ERROR, or INFO.

- **Priority**: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”

- **Severity Level**: This can be any one of the following values: ON, DEBUG, INFO, WARNING, ERROR, CRITICAL, ALERT, or ALL. (This is also sometimes referred to as the log level.)

The cluster log can be filtered on these properties using the NDB management client CLUSTERLOG command. This command affects the cluster log only, and has no effect on the node logs; debug logging in one or more node logs can be turned on and off using the ndb_mgm NODELOG DEBUG command.

The format used in a log message generated by NDB Cluster is as shown here:

```
timestamp [node_type] level -- Node node_id: message
```

Each line in the log, or log message, contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format. The timestamp value currently resolves to whole seconds only; fractional seconds are not supported.

- The `node_type`, or type of node or application which is performing the logging. In the cluster log, this is always [MgmtSrvr]; in the data node log, it is always [ndbd]. [NdbApi] and other values are possible in logs generated by NDB API applications and tools.

- The `level` of the event, sometimes also referred to as its severity level or log level. See earlier in this section, as well as Section 25.6.3.1, “NDB Cluster Logging Management Commands”, for more information about severity levels.

- The ID of the node reporting the event (node_id).

- A message containing a description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status or other information.

A sample from an actual cluster log is shown here:

```
2021-06-10 10:01:07 [MgmtSrvr] INFO -- Node 5: Start phase 5 completed (system restart)
2021-06-10 10:01:07 [MgmtSrvr] INFO -- Node 6: Start phase 5 completed (system restart)
2021-06-10 10:01:07 [MgmtSrvr] INFO -- Node 5: Start phase 6 completed (system restart)
```
For additional information, see Section 25.6.3.2, “NDB Cluster Log Events”.

25.6.3.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log and node logs. In the listing that follows, `node_id` denotes either a storage node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- **CLUSTERLOG ON**
  
  Turns the cluster log on.

- **CLUSTERLOG OFF**
  
  Turns the cluster log off.

- **CLUSTERLOG INFO**
  
  Provides information about cluster log settings.

  - **node_id CLUSTERLOG category=threshold**
    
    Logs `category` events with priority less than or equal to `threshold` in the cluster log.

  - **CLUSTERLOG FILTER severity_level**
    
    Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Default Threshold</th>
</tr>
</thead>
<tbody>
<tr>
<td>All</td>
<td>mysql-8.4.0 ndb-8.4.0</td>
</tr>
</tbody>
</table>

Note

Events are reported per data node, and that the threshold can be set to different values on different nodes.
Table 25.26 Cluster log categories, with default threshold setting

<table>
<thead>
<tr>
<th>Category</th>
<th>Default threshold (All data nodes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>STARTUP</td>
<td>7</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>7</td>
</tr>
<tr>
<td>STATISTICS</td>
<td>7</td>
</tr>
<tr>
<td>CHECKPOINT</td>
<td>7</td>
</tr>
<tr>
<td>NODERESTART</td>
<td>7</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>8</td>
</tr>
<tr>
<td>ERROR</td>
<td>15</td>
</tr>
<tr>
<td>INFO</td>
<td>7</td>
</tr>
<tr>
<td>BACKUP</td>
<td>15</td>
</tr>
<tr>
<td>CONGESTION</td>
<td>7</td>
</tr>
<tr>
<td>SCHEMA</td>
<td>7</td>
</tr>
</tbody>
</table>

The **STATISTICS** category can provide a great deal of useful data. See [Section 25.6.3.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a **STARTUP** event with a priority of 3 is not logged unless the threshold for **STARTUP** is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

<table>
<thead>
<tr>
<th>Severity Level Value</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ALERT</td>
<td>A condition that should be corrected immediately, such as a corrupted system database</td>
</tr>
<tr>
<td>2</td>
<td>CRITICAL</td>
<td>Critical conditions, such as device errors or insufficient resources</td>
</tr>
<tr>
<td>3</td>
<td>ERROR</td>
<td>Conditions that should be corrected, such as configuration errors</td>
</tr>
<tr>
<td>4</td>
<td>WARNING</td>
<td>Conditions that are not errors, but that might require special handling</td>
</tr>
<tr>
<td>5</td>
<td>INFO</td>
<td>Informational messages</td>
</tr>
<tr>
<td>6</td>
<td>DEBUG</td>
<td>Debugging messages used for <strong>NDBCLUSTER</strong> development</td>
</tr>
</tbody>
</table>

Event severity levels can be turned on or off (using **CLUSTERLOG FILTER**—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.
Event Reports Generated in NDB Cluster

Important
Cluster log levels are set on a per ndb_mgmd, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a CLUSTERLOG command in an instance of ndb_mgm connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

25.6.3.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

datetime [string] severity -- message

For example:

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

CONNECTION Events

These events are associated with connections between Cluster nodes.

Table 25.28 Events associated with connections between cluster nodes

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

**STARTUP Events**

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

**Table 25.30 Events relating to the startup of a node or cluster**

#### 25.6.3.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The NDB management client’s **CLUSTERLOG STATISTICS** command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

**Note**

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

  **Note**

  Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for Commit count to be greater than Trans count.

- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—one for the hidden unique index table, and 1 for the table on which the read takes place.

- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.
• **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

  **Note**
  A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

• **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero. Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are not counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in AttrInfoCount.

• **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

The maximum value that Concurrent Operations can have is the maximum number of operations that a TC block can support; currently, this is \((2 \times \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}\). (For more information about these configuration parameters, see the Transaction Parameters section of Section 25.4.3.6, “Defining NDB Cluster Data Nodes”.)

• **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, Abort count can sometimes be greater than Trans count.

• **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).

• **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

• **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the LOCAL_READS counter in the ndbinfo.counters table.

• **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the LOCAL_WRITES counter in the ndbinfo.counters table.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

  **Note**
  A single transaction may operate on data stored in multiple LQH blocks.

The Operations statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and
delete operations). This also includes operations used to replicate writes. For example, in a cluster with two fragment replicas, the write to the primary fragment replica is recorded in the primary LQH, and the write to the backup is recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does not include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each ndbd process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.

- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the NDB management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

**Note**

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see Section 25.6.3.1, "NDB Cluster Logging Management Commands".

### 25.6.4 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in NDB Cluster Start Phases, in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client (see Section 25.6.1, "Commands in the NDB Cluster Management Client"). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

**Start types.** There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.
Summary of NDB Cluster Start Phases

Note
Disk Data files are not removed when restarting a node using \texttt{--initial}.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.

- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (phase -1).** Prior to startup, each data node (\texttt{ndbd} process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one \texttt{ndbd} reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and \texttt{ndb_mgmd}.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The \texttt{ND BFS} and \texttt{NDBC NTR} blocks start. Data node file systems are cleared on those data nodes that were started with \texttt{--initial} option.

- **Phase 1.** In this stage, all remaining \texttt{NDB} kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

Note
When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The \texttt{NDBC NTR} kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.

- **Phase 3.** The \texttt{DBLQ H} and \texttt{D B TC} kernel blocks set up communications between them. The startup type is determined; if this is a restart, the \texttt{DBDI H} block obtains permission to perform the restart.

- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to \texttt{NoOfFragmentLogFiles}.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
• Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

• **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.

• **Phase 6.** In this phase, node groups are defined and set up.

• **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as *Started*. It is now possible for API nodes (including SQL nodes) to connect to the cluster.

• **Phase 8.** If this is a system restart, all indexes are rebuilt (by *DBDIH*).

• **Phase 9.** The node internal startup variables are reset.

• **Phase 100 (OBsolete).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.

• **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA* *handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

**25.6.5 Performing a Rolling Restart of an NDB Cluster**

This section discusses how to perform a *rolling restart* of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

**Configuration change.**

To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**NDB Cluster software upgrade or downgrade.** To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of NDB Cluster).

**Change on node host.** To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

**System reset (cluster reset).**

To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

• Start each data node process (*ndbd* or possibly *ndbmd*) with the *--initial* option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes. This also forces the removal of all Disk Data objects and files associated with those objects.
Performing a Rolling Restart of an NDB Cluster

- Create a backup using the `ndb_mgm` client `START_BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA`.

**Resource Recovery.**

To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See Rolling restarts with multiple management servers.)

2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn. Some node configuration parameters can be updated by issuing `RESTART` for each of the data nodes in the `ndb_mgm` client following the previous step. Other parameters require that the data node be stopped completely using the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndbmtcd` executable as appropriate. (A shell command such as `kill` can also be used on most Unix systems to stop a data node process, but the `STOP` command is preferred and usually simpler.)

   **Note**

   On Windows, you can also use `SC STOP` and `SC START` commands, `NET STOP` and `NET START` commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see Section 25.3.2.4, “Installing NDB Cluster Processes as Windows Services”).

   The type of restart required is indicated in the documentation for each node configuration parameter. See Section 25.4.3, “NDB Cluster Configuration Files”.

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.

- You must upgrade all nodes of the same type (management, data, or API node) before upgrading any nodes of a different type. This remains true regardless of the order in which the nodes are upgraded.

- You must upgrade all management nodes before upgrading any data nodes. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.

- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)
It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart. Due in part to this limitation, schema operations are also not supported during an online upgrade or downgrade. In addition, it is not possible to perform native backups while an upgrade or downgrade is ongoing.

Rolling restarts with multiple management servers. When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that \texttt{ndb_mgmd} checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force \texttt{ndb_mgmd} to re-read its configuration file, perform the following steps:

1. Stop all NDB Cluster \texttt{ndb_mgmd} processes.
2. Update all \texttt{config.ini} files.
3. Start a single \texttt{ndb_mgmd} with \texttt{--reload}, \texttt{--initial}, or both options as desired.
4. If you started the first \texttt{ndb_mgmd} with the \texttt{--initial} option, you must also start any remaining \texttt{ndb_mgmd} processes using \texttt{--initial}.

Regardless of any other options used when starting the first \texttt{ndb_mgmd}, you should not start any remaining \texttt{ndb_mgmd} processes after the first one using \texttt{--reload}.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the \texttt{config_generation} column of the \texttt{ndbinfo.nodes} table to keep track of which data nodes have been successfully restarted with the new configuration. See Section 25.6.17.48, "The \texttt{ndbinfo nodes Table}".

25.6.6 NDB Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of \texttt{ndb_restore}. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the \texttt{ALL STATUS} command in the \texttt{ndb_mgm} client to see when the cluster has entered single user mode. You can also check the \texttt{status} column of the \texttt{ndbinfo.nodes} table (see Section 25.6.17.48, "The \texttt{ndbinfo nodes Table}", for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node is rejected.

\textbf{Note}

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command \texttt{EXIT SINGLE USER MODE} changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is,
Adding NDB Cluster Data Nodes Online

waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- **Method 1:**
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes

- **Method 2:**
  
  Restart storage nodes prior to entering single user mode.

### 25.6.7 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

**Important**

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of fragment replicas (or the number of nodes per node group) online.

### 25.6.7.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

**Redistribution of Data.** The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

**Partial starts.** It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

**Effects on ongoing operations.** Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.
Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

Table 25.38 Data node failure handling during node group creation and table reorganization

<table>
<thead>
<tr>
<th>Failure during</th>
<th>Failure in “Old” data node</th>
<th>Failure in “New” data node</th>
<th>System Failure</th>
</tr>

<td>• If the internal commit point has not yet been reached. The table reorganization is rolled back.</td>
<td>• If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has not yet reached the internal commit point: When the cluster is restarted, the data and indexes belonging to table are distributed using only the “old” data nodes.</td>
<td></td>
</tr>
</tbody>
</table>

Dropping node groups. The ndb_mgm client supports a DROP NODEGROUP command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since
there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.

2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

   `TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

25.6.7.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using `ndbd` or `ndbmtd` binaries for the data node processes. For a more detailed example, see Section 25.6.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

   You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

   ![Important](image)

   All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

   If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.

5. Start the new data nodes.

   The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes belong.

7. Redistribute the cluster’s data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

   Exception: For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables. You should also bear in mind that using `MAX_ROWS` to set the number of partitions in this fashion is
Adding NDB Cluster Data Nodes Online

deprecated, and you should use `PARTITION_BALANCE` instead; see Section 15.1.20.12, “Setting NDB Comment Options”, for more information.

Note
This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER TABLE ... REORGANIZE PARTITION ALGORITHM=INPLACE` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

This works for space used by variable-width columns of in-memory NDB tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

25.6.7.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[nbdb default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[nbdb]
Id = 1
HostName = 198.51.100.1

[nbdb]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Note
We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:
Adding NDB Cluster Data Nodes Online

-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186 (using cleartext)
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
 id=1    @198.51.100.1  (8.4.0-ndb-8.4.0, Nodegroup: 0, *)
 id=2    @198.51.100.2  (8.4.0-ndb-8.4.0, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
 id=10   @198.51.100.10  (8.4.0-ndb-8.4.0)

[mysqld(API)]   2 node(s)
 id=20   @198.51.100.20  (8.4.0-ndb-8.4.0)
 id=21   @198.51.100.21  (8.4.0-ndb-8.4.0)

Finally, we assume that the cluster contains a single NDBCLUSTER table created as shown here:

```
USE n;
CREATE TABLE ips (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    country_code CHAR(2) NOT NULL,
    type CHAR(4) NOT NULL,
    ip_address VARCHAR(15) NOT NULL,
    addresses BIGINT UNSIGNED DEFAULT NULL,
    date BIGINT UNSIGNED DEFAULT NULL
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

**Note**

In this example, we show the single-threaded ndbd being used for the data node processes. You can also apply this example, if you are using the multithreaded ndbmtd by substituting ndbmtd for ndbd wherever it appears in the steps that follow.

**Step 1: Update configuration file.** Open the cluster global configuration file in a text editor and add [ndbd] sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the config.ini file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3

[ndbd]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
```
Adding NDB Cluster Data Nodes Online

Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

   ```
   ndb_mgm> 10 STOP
   Node 10 has shut down.
   Disconnecting to allow Management Server to shutdown
   $>
   ```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

   ```
   $> ndb_mgmd -f config.ini --reload
   2008-12-08 17:29:23 [MgmSrvr] INFO     -- NDB Cluster Management Server. 8.4.0-ndb-8.4.0
   2008-12-08 17:29:23 [MgmSrvr] INFO     -- Reading cluster configuration from 'config.ini'
   ```

   If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

   ```
   -- NDB Cluster -- Management Client --
   ndb_mgm> SHOW
   Connected to Management Server at: 198.51.100.10:1186 (using cleartext)
   Cluster Configuration
   ---------------------
   [ndbd(NDB)]     2 node(s)
   id=1    @198.51.100.1  (8.4.0-ndb-8.4.0, Nodegroup: 0, *)
   id=2    @198.51.100.2  (8.4.0-ndb-8.4.0, Nodegroup: 0)
   id=3 (not connected, accepting connect from 198.51.100.3)
   id=4 (not connected, accepting connect from 198.51.100.4)
   [ndb_mgmd(MGM)] 1 node(s)
   id=10   @198.51.100.10  (8.4.0-ndb-8.4.0)
   [mysqld(API)]   2 node(s)
   id=20   @198.51.100.20  (8.4.0-ndb-8.4.0)
   id=21   @198.51.100.21  (8.4.0-ndb-8.4.0)
   ```

**Step 3: Perform a rolling restart of the existing data nodes.** This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted
ndb_mgm> Node 1: Start initiated (version 8.4.0)
Node 1: Started (version 8.4.0)
ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
```
Adding NDB Cluster Data Nodes Online

Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 8.4.0)

ndb_mgm> Node 2: Started (version 8.4.0)

**Important**

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

**Step 4: Perform a rolling restart of all cluster API nodes.** Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL root password for a given MySQL server instance:

```command
$> mysqladmin -uroot -p password shutdown
081208 20:19:56 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
$> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.** From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```command
$> ndbd -c 198.51.100.10 --initial
```

**Note**

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

*Wait until both of the new data nodes have started before proceeding with the next step.* Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186 (using cleartext)
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (8.4.0-ndb-8.4.0, Nodegroup: 0, *)
id=2 @198.51.100.2 (8.4.0-ndb-8.4.0, Nodegroup: 0)
id=3 @198.51.100.3 (8.4.0-ndb-8.4.0, no nodegroup)
id=4 @198.51.100.4 (8.4.0-ndb-8.4.0, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (8.4.0-ndb-8.4.0)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (8.4.0-ndb-8.4.0)
id=21 @198.51.100.21 (8.4.0-ndb-8.4.0)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE_NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:
Adding NDB Cluster Data Nodes Online

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
```

```
Connected to Management Server at: 198.51.100.10:1186 (using cleartext)
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (8.4.0-ndb-8.4.0, Nodegroup: 0, *)
id=2    @198.51.100.2  (8.4.0-ndb-8.4.0, Nodegroup: 0)
```

```
id=3    @198.51.100.3  (8.4.0-ndb-8.4.0, Nodegroup: 1)
id=4    @198.51.100.4  (8.4.0-ndb-8.4.0, Nodegroup: 1)
```

```
[ndb_mgmd(MGM)] 1 node(s)
id=10  @198.51.100.10  (8.4.0-ndb-8.4.0)
```

```
[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (8.4.0-ndb-8.4.0)
id=21   @198.51.100.21  (8.4.0-ndb-8.4.0)
```

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group’s data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY
```

```
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

```
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the Per partition info section of the output, shown here in bold text):

```
$> ndb_desc -c 198.51.100.10 -d n ips -p
```

```
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NOT NULL AT=FIXED ST=MEMORY
date Bigunsigned NOT NULL AT=FIXED ST=MEMORY
```

```
-- Indexes --

</table>

You can cause the data to be redistributed among all of the data nodes by performing, for each NDB table, an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client.

**Important**

`ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` does not work on tables that were created with the `MAX_ROWS` option. Instead, use `ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=...` to reorganize such tables.

Keep in mind that using `MAX_ROWS` to set the number of partitions per table is deprecated, and you should use `PARTITION_BALANCE` instead; see Section 15.1.20.12, “Setting NDB Comment Options”, for more information.

After issuing the statement `ALTER TABLE ips ALGORITHM=INPLACE, REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```bash
$> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --

<td>13093</td>
<td>819200</td>
<td>294912</td>
</tr>
</tbody>
</table>
```

**Note**

Normally, `ALTER TABLE table_name [ALGORITHM=INPLACE,] REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new
Adding NDB Cluster Data Nodes Online

NDB Cluster node group is an exception in this regard; when used in this way, no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see Section 15.1.9, "ALTER TABLE Statement".

In addition, for each table, the `ALTER TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the Information Schema `TABLES` table:

```sql
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';
```

Note
The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

Note
Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created after the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed prior to the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER TABLE ... REORGANIZE PARTITION`.

Alternative procedure, without rolling restart. It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2
```
The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with NodeGroup = 65536, in which case nodes 1 and 2 can each be started as shown here:

```bash
$> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with NodeGroup = 65536 are treated by the management server as though you had started nodes 1 and 2 using --nowait-nodes=3,4 after waiting for a period of time determined by the setting for the StartNoNodeGroupTimeout data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

**Note**

StartNoNodeGroupTimeout must be the same for all data nodes in the cluster; for this reason, you should always set it in the [ndbd default] section of the config.ini file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```bash
$> ndbd -c 198.51.100.10 --initial
```

2. Issue the appropriate CREATE NODEGROUP command in the management client:

```bash
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the mysql client, issue ALTER TABLE ... REORGANIZE PARTITION and OPTIMIZE TABLE statements for each existing NDBCLUSTER table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

### 25.6.8 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the ndb_mgm management client. To distinguish this type of backup from a backup made using mysqldump, we sometimes refer to it as a “native” NDB Cluster backup. (For information about the creation of backups with mysqldump, see Section 6.5.4, “mysqldump — A Database Backup Program”.) Restoration of NDB Cluster backups is done using the ndb_restore utility provided with the NDB Cluster distribution; for information about ndb_restore and its use in restoring NDB Cluster backups, see Section 25.5.23, “ndb_restore — Restore an NDB Cluster Backup”.

It is also possible to create backups using multiple LDMs to achieve parallelism on the data nodes. See Section 25.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”.
25.6.8.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

• **Metadata.** The names and definitions of all database tables

• **Table records.** The data actually stored in the database tables at the time that the backup was made

• **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

• **BACKUP-backup_id.node_id.ctl**
  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

• **BACKUP-backup_id-0.node_id.data**
  A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

• **BACKUP-backup_id.node_id.log**
  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

25.6.8.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 25.6.8.3, “Configuration for NDB Cluster Backups”.)

The `START BACKUP` command is used to create a backup, and has the syntax shown here:

```plaintext
START BACKUP [backup_id]
  [encryption_option]
  [wait_option]
  [snapshot_option]

encryption_option:
ENCRYPT [PASSWORD=password]
password:
  {'password_string' | "password_string"}

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT
snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `Backup failed: file already exists`. If used, the `backup_id` must follow immediately after the `START BACKUP` keywords, before any other options are used.
START BACKUP supports the creation of encrypted backups using ENCRYPT PASSWORD=password. The password must meet all of the following requirements:

- Uses any of the printable ASCII characters except !, ', "", $, $, \, and ^
- Is no more than 256 characters in length
- Is enclosed by single or double quotation marks

When ENCRYPT PASSWORD='password' is used, the backup data record and log files written by each data node are encrypted with a key derived from the user-provided password and a randomly-generated salt using a key derivation function (KDF) that employs the PBKDF2-SHA256 algorithm to generate a symmetric encryption key for that file. This function has the form shown here:

\[
key = \text{KDF}(\text{random\_salt}, \text{password})
\]

The key so generated is then used to encrypt the backup data using AES 256 CBC inline, and symmetric encryption is employed for encrypting the backup files set (with the generated key).

Note

NDB Cluster never saves the user-furnished password or generated encryption key.

The PASSWORD option can be omitted from encryption_option. In this case, the management client prompts the user for a password.

It is possible using PASSWORD to set an empty password (' ' or "") , but this is not recommended.

An encrypted backup can be decrypted using any of the following commands:

- ndb_restore --decrypt --backup-password=password
- ndbxfrm --decrypt-password=password input_file output_file
- ndb_print_backup_file -P password file_name
- ndb_restore --decrypt --backup-password-from-stdin
- ndbxfrm --decrypt-password-from-stdin input_file output_file
- ndb_print_backup_file --backup-password-from-stdin file_name
- ndb_mgm --backup-password-from-stdin --execute "START BACKUP ..."

See the descriptions of these programs for more information, such as additional options that may be required.

The wait_option can be used to determine when control is returned to the management client after a START BACKUP command is issued, as shown in the following list:

- If NOWAIT is specified, the management client displays a prompt immediately, as seen here:

  ndb_mgm> START BACKUP NOWAIT
  ndb_mgm>

  In this case, the management client can be used even while it prints progress information from the backup process.

- With WAIT_STARTED the management client waits until the backup has started before returning control to the user, as shown here:

  ndb_mgm> START BACKUP WAIT_STARTED
Online Backup of NDB Cluster

Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1

- **WAIT COMPLETED** causes the management client to wait until the backup process is complete before returning control to the user.

**WAIT COMPLETED** is the default.

A **snapshot_option** can be used to determine whether the backup matches the state of the cluster when **START BACKUP** was issued, or when it was completed. **SNAPSHOTSTART** causes the backup to match the state of the cluster when the backup began; **SNAPSHOTEND** causes the backup to reflect the state of the cluster when the backup was finished. **SNAPSHOTEND** is the default, and matches the behavior found in previous NDB Cluster releases.

**Note**

If you use the **SNAPSHOTSTART** option with **START BACKUP**, and the **CompressedBackup** parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a **wait_option** and a **snapshot_option** are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (**ndb_mgm**), if it not running already.

2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

   ```
   ndb_mgm> START BACKUP
   Waiting for completed, this may take several minutes
   Node 2: Backup 1 started from node 1
   Node 2: Backup 1 started from node 1 completed
   StartGCP: 177 StopGCP: 180
   #Records: 7362 #LogRecords: 0
   Data: 453648 bytes Log: 0 bytes
   ndb_mgm>
   ```

3. When the backup has started the management client displays this message:

   ```
   Backup backup_id started from node node_id
   ```

   **backup_id** is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. **node_id** is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

   ```
   Node 2: Backup 1 started from node 1
   ```

4. The management client indicates with a message like this one that the backup has started:

   ```
   Backup backup_id started from node node_id completed
   ```

   As is the case for the notification that the backup has started, **backup_id** is the unique identifier for this particular backup, and **node_id** is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information
including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

<table>
<thead>
<tr>
<th>Node 2: Backup 1 started from node 1 completed</th>
</tr>
</thead>
<tbody>
<tr>
<td>StartGCP: 177 StopGCP: 180</td>
</tr>
<tr>
<td>#Records: 7362 #LogRecords: 0</td>
</tr>
<tr>
<td>Data: 453648 bytes Log: 0 bytes</td>
</tr>
</tbody>
</table>

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```bash
$> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the `backup` directory.

**Cancelling backups.** To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.

2. Execute this command:

   ```bash
   ndb_mgm> ABORT BACKUP backup_id
   ```

   The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client acknowledges the abort request with `Abort of backup backup_id ordered`.

   **Note**

   At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client reports this fact in a manner similar to what is shown here:

   ```
   Node 1: Backup 3 started from 5 has been aborted.
   Error: 1321 - Backup aborted by user request: Permanent error: User defined error
   Node 3: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
   Node 2: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
   Node 4: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
   ```

   In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

   **Note**

   There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.
Online Backup of NDB Cluster

The Backup backup_id started from node management_node_id has been aborted messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
$> ndb_mgm -e "ABORT BACKUP backup_id"
```

**Note**

If there is no backup having the ID backup_id running when an ABORT BACKUP is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 25.6.8.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- **BackupDataBufferSize**
  
The amount of memory used to buffer data before it is written to disk.

- **BackupLogBufferSize**
  
The amount of memory used to buffer log records before these are written to disk.

- **BackupMemory**
  
The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- **BackupWriteSize**
  
The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- **BackupMaxWriteSize**
  
The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

In addition, CompressedBackup causes NDB to use compression when creating and writing to backup files.

More detailed information about these parameters can be found in Backup Parameters.

You can also set a location for the backup files using the BackupDataDir configuration parameter. The default is FileSystemPath/BACKUP/BACKUP-backup_id.

You can enforce encryption of backup files by setting RequireEncryptedBackup to 1; this prevents the creation of backups without specifying ENCRYPT PASSWORD=password as part of a START BACKUP command.

### 25.6.8.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

**Important**

If you have set BackupDataBufferSize and BackupLogBufferSize and their sum is greater than 4MB, then you must also set BackupMemory as well.
You should also make sure that there is sufficient space on the hard drive partition of the backup target.

**NDB** does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an NDB Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

### 25.6.8.5 Taking an NDB Backup with Parallel Data Nodes

It is possible to take a backup with multiple local data managers (LDMs) acting in parallel on the data nodes. For this to work, all data nodes in the cluster must use multiple LDMs, and each data node must use the same number of LDMs. This means that all data nodes must run `ndbmd` (**ndbd** is single-threaded and thus always has only one LDM) and they must be configured to use multiple LDMs before taking the backup; `ndbmd` by default runs in single-threaded mode. You can cause them to use multiple LDMs by choosing an appropriate setting for one of the multi-threaded data node configuration parameters `MaxNoOfExecutionThreads` or `ThreadConfig`. Keep in mind that changing these parameters requires a restart of the cluster; this can be a rolling restart. In addition, the `EnableMultithreadedBackup` parameter must be set to 1 for each data node (this is the default).

Depending on the number of LDMs and other factors, you may also need to increase `NoOfFragmentLogParts`. If you are using large Disk Data tables, you may also need to increase `DiskPageBufferMemory`. As with single-threaded backups, you may also want or need to make adjustments to settings for `BackupDataBufferSize`, `BackupMemory`, and other configuration parameters relating to backups (see **Backup parameters**).

Once all data nodes are using multiple LDMs, you can take the parallel backup using the `START BACKUP` command in the NDB management client just as you would if the data nodes were running `ndbd` (or `ndbmd` in single-threaded mode); no additional or special syntax is required, and you can specify a backup ID, wait option, or snapshot option in any combination as needed or desired.

Backups using multiple LDMs create subdirectories, one per LDM, under the directory `BACKUP/backup_id` (which in turn resides under the `BackupDataDir`) on each data node; these subdirectories are named `BACKUP-1-OF-N/`, `BACKUP-2-OF-N/`, and so on, up to `BACKUP-N-OF-N/`, where `backup_id` is the backup ID used for this backup and `N` is the number of LDMs per data node. Each of these subdirectories contains the usual backup files `BACKUP-0.node_id.Data`, `BACKUP-backup_id.node_id.ctl`, and `BACKUP-backup_id.node_id.log`, where `node_id` is the node ID of this data node.

`ndb_restore` automatically checks for the presence of the subdirectories just described; if it finds them, it attempts to restore the backup in parallel. For information about restoring backups taken with multiple LDMs, see **Restoring from a backup taken in parallel**.

To force creation of a single-threaded backup, set `EnableMultithreadedBackup = 0` for all data nodes (you can do this by setting the parameter in the `[ndbd default]` section of the `config.ini` global configuration file). It is also possible to restore a parallel backup to a cluster running an older version of **NDB**. See **Restoring an NDB backup to a previous version of NDB Cluster**, for more information.

### 25.6.9 Importing Data Into MySQL Cluster

It is common when setting up a new instance of NDB Cluster to need to import data from an existing NDB Cluster, instance of MySQL, or other source. This data is most often available in one or more of the following formats:

- An SQL dump file such as produced by `mysqldump`. This can be imported using the `mysql` client, as shown later in this section.
MySQL Server Usage for NDB Cluster

- A CSV file produced by `mysqldump` or other export program. Such files can be imported into NDB using `LOAD DATA INFILE` in the `mysql` client, or with the `ndb_import` utility provided with the NDB Cluster distribution. For more information about the latter, see Section 25.5.13, “ndb_import — Import CSV Data Into NDB”.

- A native NDB backup produced using `START BACKUP` in the NDB management client. To import a native backup, you must use the `ndb_restore` program that comes as part of NDB Cluster. See Section 25.5.23, “ndb_restore — Restore an NDB Cluster Backup”, for more about using this program.

When importing data from an SQL file, it is often not necessary to enforce transactions or foreign keys, and temporarily disabling these features can speed up the import process greatly. This can be done using the `mysql` client, either from a client session, or by invoking it on the command line. Within a `mysql` client session, you can perform the import using the following SQL statements:

```
SET ndb_use_transactions=0;
SET foreign_key_checks=0;
source path/to/dumpfile;
SET ndb_use_transactions=1;
SET foreign_key_checks=1;
```

When performing the import in this fashion, you must enable `ndb_use_transaction` and `foreign_key_checks` again following execution of the `mysql` client's `source` command. Otherwise, it is possible for later statements in same session may also be executed without enforcing transactions or foreign key constraints, and which could lead to data inconsistency.

From the system shell, you can import the SQL file while disabling enforcement of transaction and foreign keys by using the `mysql` client with the `--init-command` option, like this:

```
$> mysql --init-command='SET ndb_use_transactions=0; SET foreign_key_checks=0' < path/to/dumpfile
```

It is also possible to load the data into an InnoDB table, and convert it to use the NDB storage engine afterwards using `ALTER TABLE ... ENGINE NDB`). You should take into account, especially for many tables, that this may require a number of such operations; in addition, if foreign keys are used, you must mind the order of the `ALTER TABLE` statements carefully, due to the fact that foreign keys do not work between tables using different MySQL storage engines.

You should be aware that the methods described previously in this section are not optimized for very large data sets or large transactions. Should an application really need big transactions or many concurrent transactions as part of normal operation, you may wish to increase the value of the `MaxNoOfConcurrentOperations` data node configuration parameter, which reserves more memory to allow a data node to take over a transaction if its transaction coordinator stops unexpectedly.

You may also wish to do this when performing bulk `DELETE` or `UPDATE` operations on NDB Cluster tables. If possible, try to have applications perform these operations in chunks, for example, by adding `LIMIT` to such statements.

If a data import operation does not complete successfully, for whatever reason, you should be prepared to perform any necessary cleanup including possibly one or more `DROP TABLE` statements, `DROP DATABASE` statements, or both. Failing to do so may leave the database in an inconsistent state.

### 25.6.10 MySQL Server Usage for NDB Cluster

`mysqld` is the traditional MySQL server process. To be used with NDB Cluster, `mysqld` needs to be built with support for the NDB storage engine, as it is in the precompiled binaries available from https://dev.mysql.com/downloads/. If you build MySQL from source, you must invoke `CMake` with the `--with-ndb=1` or (deprecated) `--with-ndbcluster=1` option to include support for NDB.

For more information about compiling NDB Cluster from source, see Section 25.3.1.4, “Building NDB Cluster from Source on Linux”, and Section 25.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”.

---

4285
MySQL Server Usage for NDB Cluster

(For information about `mysqld` options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see Section 25.4.3.9, “MySQL Server Options and Variables for NDB Cluster”.)

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
$> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 25.4.3.3, “NDB Cluster Connection Strings”, for more information on connection strings.

Given this information, the MySQL server can act as a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It is fully aware of all cluster data nodes as well as their status, and establishes connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
   Id: 1
   User: system user
   Host: db
   Command: Daemon
   Time: 1
   State: Waiting for event from ndbcluster
   Info: NULL
```

**Important**

To participate in an NDB Cluster, the `mysqld` process must be started with both the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it...
NDB Cluster Disk Data Tables

NDB Cluster supports storing nonindexed columns of NDB tables on disk, rather than in RAM. Column data and logging metadata are kept in data files and undo log files, conceptualized as tablespaces and log file groups, as described in the next section—see Section 25.6.11.1, "NDB Cluster Disk Data Objects".

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see Disk Data Configuration Parameters, and Disk Data and GCP Stop errors.

You should also set the DiskDataUsingSameDisk data node configuration parameter to false when using separate disks for Disk Data files.

For more information, see the following:

- Disk Data file system parameters.
- Disk Data latency parameters
- Section 25.6.17.32, “The ndbinfo diskstat Table”
- Section 25.6.17.33, “The ndbinfo diskstats_1sec Table”
- Section 25.6.17.50, “The ndbinfo pgman_time_track_stats Table”

25.6.11.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using the following objects:

- Tablespace: Acts as containers for other Disk Data objects. A tablespace contains one or more data files and one or more undo log file groups.

- Data file: Stores column data. A data file is assigned directly to a tablespace.

- Undo log file: Contains undo information required for rolling back transactions. Assigned to an undo log file group.

- log file group: Contains one or more undo log files. Assigned to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in ndb_node_id_fs in the DataDir specified in the NDB Cluster config.ini file, and where node_id is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

Undo log files are used only by Disk Data tables, and are not needed or used by NDB tables that are stored in memory only.

NDB Cluster tablespaces and log file groups are not implemented as files.

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named dd1.
Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an undofile).

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.

3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the mysql client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named lg_1 using CREATE LOGFILE GROUP. This log file group is to be made up of two undo log files, which we name undo_1.log and undo_2.log, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add undo_1.log to lg_1 in this CREATE LOGFILE GROUP statement:

   ```sql
   CREATE LOGFILE GROUP lg_1
   ADD UNDOFILE 'undo_1.log'
   INITIAL_SIZE 16M
   UNDO_BUFFER_SIZE 2M
   ENGINE NDBCLUSTER;
   ```

   To add undo_2.log to the log file group, use the following ALTER LOGFILE GROUP statement:

   ```sql
   ALTER LOGFILE GROUP lg_1
   ADD UNDOFILE 'undo_2.log'
   INITIAL_SIZE 12M
   ENGINE NDBCLUSTER;
   ```

Some items of note:

- The .log file extension used here is not required. We employ it merely to make the log files easily recognizable.

- Every CREATE LOGFILE GROUP and ALTER LOGFILE GROUP statement must include an ENGINE option. The only permitted values for this option are NDBCLUSTER and NDB.

   Important

   There can exist at most one log file group in the same NDB Cluster at any given time.

   - When you add an undo log file to a log file group using ADD UNDOFILE 'filename', a file with the name filename is created in the ndb_node_id_fs directory within the DataDir of each data node in the cluster, where node_id is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the ALTER LOGFILE GROUP statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named undo_2.log and each file is 12 MB in size.

   - UNDO_BUFFER_SIZE is limited by the amount of system memory available.

   - See Section 15.1.16, “CREATE LOGFILE GROUP Statement”, and Section 15.1.6, “ALTER LOGFILE GROUP Statement”, for more information about these statements.

2. Now we can create a tablespace—an abstract container for files used by Disk Data tables to store data. A tablespace is associated with a particular log file group; when creating a new tablespace, you must specify the log file group it uses for undo logging. You must also specify at least one data
Assume that we wish to create a tablespace named ts_1 which uses lg_1 as its log file group. We want the tablespace to contain two data files, named data_1.dat and data_2.dat, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for INITIAL_SIZE is 128 MB.) We can do this using two SQL statements, as shown here:

```sql
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M;
```

The `CREATE TABLESPACE` statement creates a tablespace ts_1 with the data file data_1.dat, and associates ts_1 with log file group lg_1. The `ALTER TABLESPACE` adds the second data file (data_2.dat).

Some items of note:

- As is the case with the .log file extension used in this example for undo log files, there is no special significance for the .dat file extension; it is used merely for easy recognition.
- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named data_2.dat, and each file is 48 MB in size.
- NDB reserves 4% of each tablespace for use during data node restarts. This space is not available for storing data.
- `CREATE TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. For NDB tablespaces, `ALTER TABLESPACE` accepts an `ENGINE` clause only for `ALTER TABLESPACE ... ADD DATAFILE; ENGINE` is rejected for any other `ALTER TABLESPACE` statement. For NDB tablespaces, the only permitted values for the `ENGINE` option are `NDBCLUSTER` and `NDB`.
- Allocation of extents is performed in round-robin fashion among all data files used by a given tablescape.
- For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see Section 15.1.21, "CREATE TABLESPACE Statement", and Section 15.1.10, "ALTER TABLESPACE Statement".

3. Now it is possible to create a table whose unindexed columns are stored on disk using files in tablespace ts_1:

```sql
CREATE TABLE dt_1 (
  member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  last_name VARCHAR(50) NOT NULL,
  first_name VARCHAR(50) NOT NULL,
  dob DATE NOT NULL,
  joined DATE NOT NULL,
  INDEX(last_name, first_name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```
TABLESPACE ts_1 STORAGE DISK tells the NDB storage engine to use tablespace ts_1 for data storage on disk.

Once table ts_1 has been created as shown, you can perform INSERT, SELECT, UPDATE, and DELETE statements on it just as you would with any other MySQL table.

It is also possible to specify whether an individual column is stored on disk or in memory by using a STORAGE clause as part of the column's definition in a CREATE TABLE or ALTER TABLE statement. STORAGE DISK causes the column to be stored on disk, and STORAGE MEMORY causes in-memory storage to be used. See Section 15.1.20, "CREATE TABLE Statement", for more information.

You can obtain information about the NDB disk data files and undo log files just created by querying the FILES table in the INFORMATION_SCHEMA database, as shown here:

```
mysql> SELECT FILE_NAME AS File, FILE_TYPE AS Type, TABLESPACE_NAME AS Tablespace, TABLE_NAME AS Name, LOGFILE_GROUP_NAME AS 'File group', FREE_EXTENTS AS Free, TOTAL_EXTENTS AS Total FROM INFORMATION_SCHEMA.FILES WHERE ENGINE='ndbcluster';
```

<table>
<thead>
<tr>
<th>File</th>
<th>Type</th>
<th>Tablespace</th>
<th>Name</th>
<th>'File group'</th>
<th>Free</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>./undo_1.log</td>
<td>UNDO LOG</td>
<td>lg_1</td>
<td>NULL</td>
<td>lg_1</td>
<td>0</td>
<td>4194304</td>
</tr>
<tr>
<td>./undo_2.log</td>
<td>UNDO LOG</td>
<td>lg_1</td>
<td>NULL</td>
<td>lg_1</td>
<td>0</td>
<td>3145728</td>
</tr>
<tr>
<td>./data_1.dat</td>
<td>DATAFILE</td>
<td>ts_1</td>
<td>NULL</td>
<td>lg_1</td>
<td>32</td>
<td>32</td>
</tr>
<tr>
<td>./data_2.dat</td>
<td>DATAFILE</td>
<td>ts_1</td>
<td>NULL</td>
<td>lg_1</td>
<td>48</td>
<td>48</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)

For more information and examples, see Section 28.3.15, "The INFORMATION_SCHEMA FILES Table".

### Indexing of columns implicitly stored on disk

For table dt_1 as defined in the example just shown, only the dob and joined columns are stored on disk. This is because there are indexes on the id, last_name, and first_name columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

You cannot add an index to a column that has been explicitly declared STORAGE DISK, without first changing its storage type to MEMORY; any attempt to do so fails with an error. A column which implicitly uses disk storage can be indexed; when this is done, the column's storage type is changed to MEMORY automatically. By "implicitly", we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following CREATE TABLE statement (using the tablespace ts_1 defined previously), columns c2 and c3 use disk storage implicitly:

```
mysql> CREATE TABLE ti (  
-> c1 INT PRIMARY KEY,  
-> c2 INT,              
-> c3 INT,              
-> c4 INT              
-> )  
-> STORAGE DISK  
-> TABLESPACE ts_1  
-> ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.31 sec)
```

Because c2, c3, and c4 are themselves not declared with STORAGE DISK, it is possible to index them. Here, we add indexes to c2 and c3, using, respectively, CREATE INDEX and ALTER TABLE:

```
mysql> CREATE INDEX i1 ON ti(c2);
```
NDB Cluster Disk Data Tables

Query OK, 0 rows affected (2.72 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0  Duplicates: 0  Warnings: 0

SHOW CREATE TABLE confirms that the indexes were added.

You can see using `ndb_desc` that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

`$> ./ndb_desc -d test t1
-- t1 --
Version: 33554433
Fragment type: HashMapPartition

-- Indexes --
PRIMAR Y KEY (c1) - UniqueHashIndex
i2 (c3) - OrderedIndex
PRIMARY (c1) - OrderedIndex
i1 (c2) - OrderedIndex

Performance note. The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You can use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`; relative paths are calculated with respect to the data node's data directory.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. This is also true for dropping these objects, subject to the following constraints:
• A log file group cannot be dropped as long as any tablespaces use it.
• A tablespace cannot be dropped as long as it contains any data files.
• You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
• It is not possible to drop files created in association with a different tablespace other than the one with which the files were created.

For example, to drop all the objects created so far in this section, you can use the following statements:

```sql
mysql> DROP TABLE dt_1;
mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_2.dat';
mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_1.dat';
mysql> DROP TABLESPACE ts_1;
mysql> DROP LOGFILE GROUP lg_1;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

**Note**

Older versions of NDB Cluster used an `ENGINE` clause with `ALTER TABLESPACE ... DROP DATAFILE` and `DROP TABLESPACE`. In NDB 8.4 and later, it is no longer supported with either of these statements.

### 25.6.11.2 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

• Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see Section 13.7, “Data Type Storage Requirements”.

You can obtain an estimate the amount of space available in data files and undo log files by querying the Information Schema `FILES` table. For more information and examples, see Section 28.3.15, “The INFORMATION_SCHEMA FILES Table”.

**Note**

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

• In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.

• Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

**Important**

Starting the cluster with the `--initial` option does not remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.
Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

### 25.6.12 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster supports online table schema changes using `ALTER TABLE ...` `ALGORITHM=DEFAULT|INPLACE|COPY`. NDB Cluster handles `COPY` and `INPLACE` as described in the next few paragraphs.

For `ALGORITHM=COPY`, the `mysqld` NDB Cluster handler performs the following actions:

- Tells the data nodes to create an empty copy of the table, and to make the required schema changes to this copy.
- Reads rows from the original table, and writes them to the copy.
- Tells the data nodes to drop the original table and then to rename the copy.

We sometimes refer to this as a “copying” or “offline” `ALTER TABLE`.

DML operations are not permitted concurrently with a copying `ALTER TABLE`.

The `mysqld` on which the copying `ALTER TABLE` statement is issued takes a metadata lock, but this is in effect only on that `mysqld`. Other NDB clients can modify row data during a copying `ALTER TABLE`, resulting in inconsistency.

For `ALGORITHM=INPLACE`, the NDB Cluster handler tells the data nodes to make the required changes, and does not perform any copying of data.

We also refer to this as a “non-copying” or “online” `ALTER TABLE`.

A non-copying `ALTER TABLE` allows concurrent DML operations.

`ALGORITHM=INSTANT` is not supported by NDB 8.4.

Regardless of the algorithm used, the `mysqld` takes a Global Schema Lock (GSL) while executing `ALTER TABLE`; this prevents execution of any (other) DDL or backups concurrently on this or any other SQL node in the cluster. This is normally not problematic, unless the `ALTER TABLE` takes a very long time.

---

**Note**

Some older releases of NDB Cluster used a syntax specific to NDB for online `ALTER TABLE` operations. That syntax has since been removed.

Operations that add and drop indexes on variable-width columns of NDB tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in an NDB Cluster (but see **Limitations of NDB online operations**, later in this section). Such operations do not require single user mode for NDB table alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

`ALGORITHM=INPLACE` can be used to perform online `ADD COLUMN`, `ADD INDEX` (including `CREATE INDEX` statements), and `DROP INDEX` operations on NDB tables. Online renaming of NDB tables is also supported.

Disk-based columns cannot be added to NDB tables online. This means that, if you wish to add an in-memory column to an NDB table that uses a table-level `STORAGE DISK` option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace `ts1`—suppose that you create table `t1` as follows:

```sql
mysql> CREATE TABLE t1 (```````````````
Online Operations with ALTER TABLE in NDB Cluster

> c1 INT NOT NULL PRIMARY KEY,
> c2 VARCHAR(30)
> )
> TABLESPACE ts1 STORAGE DISK
> ENGINE NDB;

Query OK, 0 rows affected (1.73 sec)
Records: 0 Duplicates: 0 Warnings: 0

You can add a new in-memory column to this table online as shown here:

mysql> ALTER TABLE t1
>    ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,
>    ALGORITHM=INPLACE;
Query OK, 0 rows affected (1.25 sec)
Records: 0 Duplicates: 0 Warnings: 0

This statement fails if the STORAGE MEMORY option is omitted:

mysql> ALTER TABLE t1
>    ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,
>    ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:
Adding column(s) or add/reorganize partition not supported online. Try
ALGORITHM=COPY.

If you omit the COLUMN_FORMAT DYNAMIC option, the dynamic column format is employed
automatically, but a warning is issued, as shown here:

mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1478
Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will
become FIXED

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) NOT NULL,
  `c2` varchar(30) DEFAULT NULL,
  `c3` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,
  `c4` int(11) /*!50606 STORAGE MEMORY */ DEFAULT NULL,
  PRIMARY KEY (`c1`) ) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.03 sec)

Note

The STORAGE and COLUMN_FORMAT keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a CREATE TABLE or ALTER TABLE statement results in an error.

It is also possible to use the statement ALTER TABLE ... REORGANIZE PARTITION,
ALGORITHM=INPLACE with no partition_names INTO (partition_definitions) option on
NDB tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added to the cluster online. This does not perform any defragmentation, which requires an OPTIMIZE TABLE or null ALTER TABLE statement. For more information, see Section 25.6.7, “Adding NDB Cluster Data Nodes Online”.

Limitations of NDB online operations

Online DROP COLUMN operations are not supported.
Online ALTER TABLE, CREATE INDEX, or DROP INDEX statements that add columns or add or drop indexes are subject to the following limitations:

- A given online ALTER TABLE can use only one of ADD COLUMN, ADD INDEX, or DROP INDEX. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.

- The table being altered is not locked with respect to API nodes other than the one on which an online ALTER TABLE ADD COLUMN, ADD INDEX, or DROP INDEX operation (or CREATE INDEX or DROP INDEX statement) is run. However, the table is locked against any other operations originating on the same API node while the online operation is being executed.

- The table to be altered must have an explicit primary key; the hidden primary key created by the NDB storage engine is not sufficient for this purpose.

- The storage engine used by the table cannot be changed online.

- The tablespace used by the table cannot be changed online. Statements such as ALTER TABLE ndb_table ... ALGORITHM=INPLACE, TABLESPACE=new_tablespace are specifically disallowed.

- When used with NDB Cluster Disk Data tables, it is not possible to change the storage type (DISK or MEMORY) of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use ALGORITHM=COPY in the statement that adds or drops the index.

Columns to be added online cannot use the BLOB or TEXT type, and must meet the following criteria:

- The columns must be dynamic; that is, it must be possible to create them using COLUMN_FORMAT DYNAMIC. If you omit the COLUMN_FORMAT DYNAMIC option, the dynamic column format is employed automatically.

- The columns must permit NULL values and not have any explicit default value other than NULL. Columns added online are automatically created as DEFAULT NULL, as can be seen here:

```
mysql> CREATE TABLE t2 (  
  > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY  
  > ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)
```

```
mysql> ALTER TABLE t2  
  > ADD COLUMN c2 INT,  
  > ADD COLUMN c3 INT,  
  > ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)
```

```
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t2` (  
`c1` int(11) NOT NULL AUTO_INCREMENT,  
`c2` int(11) DEFAULT NULL,  
`c3` int(11) DEFAULT NULL,  
PRIMARY KEY (`c1`)  
) ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)
```

- The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the FIRST keyword, the statement fails with an error.

- Existing table columns cannot be reordered online.

For online ALTER TABLE operations on NDB tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the CREATE TABLE and ALTER TABLE statements just shown for the sake of clarity):
Privilege Synchronization and NDB_STORED_USER

Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table's primary key, which may also be FIXED, as shown here:

```
CREATE TABLE t3 (
    c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED
) ENGINE=NDB;
```

```
ALTER TABLE t3 ADD COLUMN c2 INT,
    ALGORITHM=INPLACE;
```

```
SHOW WARNINGS;
+---------------------------+-------------------+-----------------------+
| Level | Code | Message |
+---------------------------+-------------------+-----------------------+
| Warning | 1478 | Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN |
+---------------------------+-------------------+-----------------------+
```

Columns are not converted from FIXED to DYNAMIC column format by renaming operations. For more information about COLUMN_FORMAT, see Section 15.1.20, "CREATE TABLE Statement".

The KEY, CONSTRAINT, and IGNORE keywords are supported in ALTER TABLE statements using ALGORITHM=INPLACE.

Setting MAX_ROWS to 0 using an online ALTER TABLE statement is disallowed. You must use a copying ALTER TABLE to perform this operation. (Bug #21960004)

25.6.13 Privilege Synchronization and NDB_STORED_USER

Privilege synchronization is the mechanism used by NDB Cluster for sharing and synchronizing users, roles, and privileges between SQL nodes. This can be enabled by granting the NDB_STORED_USER privilege. See the description of the privilege for usage information.

NDB_STORED_USER is printed in the output of SHOW GRANTS as with any other privilege, as shown here:

```
SHOW GRANTS for 'jon'@'localhost';
```

You can also verify that privileges are shared for this account using the ndb_select_all utility supplied with NDB Cluster, like this (some output wrapped to preserve formatting):
ndb_sql_metadata is a special NDB table that is not visible using the mysql or other MySQL client.

A statement granting the NDB_STORED_USER privilege, such as GRANT NDB_STORED_USER ON *.* TO 'cluster_app_user'@'localhost', works by directing NDB to create a snapshot using the queries SHOW CREATE USER cluster_app_user@localhost and SHOW GRANTS FOR cluster_app_user@localhost, then storing the results in ndb_sql_metadata. Any other SQL nodes are then requested to read and apply the snapshot. Whenever a MySQL server starts up and joins the cluster as an SQL node it executes these stored CREATE USER and GRANT statements as part of the cluster schema synchronization process.

Whenever an SQL statement is executed on an SQL node other than the one where it originated, the statement is run in a utility thread of the NDBCLUSTER storage engine; this is done within a security environment equivalent to that of the MySQL replication replica applier thread.

An SQL node performing a change to user privileges takes a global lock before doing so, which prevents deadlocks by concurrent ACL operations on different SQL nodes.

You should keep in mind that, because shared schema change operations are performed synchronously, the next shared schema change following a change to any shared user or users serves as a synchronization point. Any pending user changes run to completion before the schema change distribution can begin; after this the schema change itself runs synchronously. For example, if a DROP DATABASE statement follows a DROP USER of a distributed user, the drop of the database cannot take place until the drop of the user has completed on all SQL nodes.

In the event that multiple GRANT, REVOKE, or other user administration statements from multiple SQL nodes cause privileges for a given user to diverge on different SQL nodes, you can fix this problem by issuing GRANT NDB_STORED_USER for this user on an SQL node where the privileges are known to be correct; this causes a new snapshot of the privileges to be taken and synchronized to the other SQL nodes.

Note
NDB Cluster 8.4 does not support distribution of MySQL users and privileges across SQL nodes in an NDB Cluster by altering the MySQL privilege tables such that they use the NDB storage engine as was done in older releases (NDB 7.6 and earlier—see Distributed Privileges Using Shared Grant Tables).

25.6.14 File System Encryption for NDB Cluster

The following sections provide information about NDB data node file system encryption.

25.6.14.1 NDB File System Encryption Setup and Usage

Encryption of file system: To enable encryption of a previously unencrypted file system, the following steps are required:

1. Set the required data node parameters in the [ndbd default] section of the config.ini file, as shown here:

   ```ini
   [ndbd default]
   EncryptedFileSystem= 1
   ```

   These parameters must be set as shown on all data nodes.
2. Start the management server with either \texttt{--initial} or \texttt{--reload} to cause it to read the updated configuration file.

3. Perform a rolling initial start (or restart) of all the data nodes (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”): Start each data node with \texttt{--initial}; in addition, supply either of the options \texttt{--filesystem-password} or \texttt{--filesystem-password-from-stdin}, plus a password, to each data node process. When you supply the password on the command line, a warning is shown, similar to this one:

\begin{verbatim}
> ndbmt -c 127.0.0.1 --filesystem-password=ndbsecret
ndbmtd: [Warning] Using a password on the command line interface can be insecure.
2022-08-22 16:17:58 [ndbd] INFO -- Angel connected to '127.0.0.1:1186'
\end{verbatim}

\texttt{--filesystem-password} can accept the password form a file, \texttt{tty}, or \texttt{stdin}; \texttt{--filesystem-password-from-stdin} accepts the password from \texttt{stdin} only. The latter protects the password from exposure on the process command line or in the file system, and allows for the possibility of passing it from another secure application.

You can also place the password in a \texttt{my.cnf} file that can be read by the data node process, but not by other users of the system. Using the same password as in the previous example, the relevant portion of the file should look like this:

\begin{verbatim}
[ndbd]
filesystem-password=ndbsecret
\end{verbatim}

You can also prompt the user starting the data node process to supply the encryption password when doing so, by using the \texttt{--filesystem-password-from-stdin} option in the \texttt{my.cnf} file instead, like this:

\begin{verbatim}
[ndbd]
filesystem-password-from-stdin
\end{verbatim}

In this case, the user is prompted for the password when starting the data node process, as shown here:

\begin{verbatim}
> ndbmt -c 127.0.0.1
Enter filesystem password: ********
2022-08-22 16:36:00 [ndbd] INFO -- Angel connected to '127.0.0.1:1186'
2022-08-22 16:36:00 [ndbd] INFO -- Angel allocated nodeid: 5
> 
\end{verbatim}

Regardless of the method used, the format of the encryption password is the same as that used for passwords for encrypted backups (see Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”); the password must be supplied when starting each data node process; otherwise the data node process cannot start. This is indicated by the following message in the data node log:

\begin{verbatim}
> tail -n2 ndb_5_out.log
2022-08-22 16:08:30 [ndbd] INFO -- Data node configured to have encryption but password not provided
\end{verbatim}

When restarted as just described, each data node clears its on-disk state, and rebuilds it in encrypted form.

\textit{Rotation of File system password}: To update the encryption password used by the data nodes, perform a rolling initial restart of the data nodes, supplying the new password to each data node when restarting it using \texttt{--filesystem-password} or \texttt{--filesystem-password-from-stdin}.

\textit{Decryption of file system}: To remove encryption from an encrypted file system, do the following:

1. In the \texttt{[ndbd default]} section of the \texttt{config.ini} file, set \texttt{EncryptedFileSystem = OFF}. 

\leavevmode
2. Restart the management server with `--initial` or `--reload`.

3. Perform a rolling initial restart of the data nodes. Do not use any password-related options when restarting the node binaries.

When restarted, each data node clears its on-disk state, and rebuilds it in unencrypted form.

To see whether file system encryption is properly configured, you can use a query against the `ndbinfo config_values` and `config_params` tables similar to this one:

```sql
mysql> SELECT v.node_id AS Node, p.param_name AS Parameter, v.config_value AS Value
    -> FROM ndbinfo.config_values v
    -> JOIN ndbinfo.config_params p
    -> ON v.config_param=p.param_number
    -> WHERE p.param_name='EncryptedFileSystem';
```

```
+------+----------------------+-------+
<table>
<thead>
<tr>
<th>Node</th>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>EncryptedFileSystem</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>EncryptedFileSystem</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>EncryptedFileSystem</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>EncryptedFileSystem</td>
<td>1</td>
</tr>
</tbody>
</table>
+------+----------------------+-------+
```

Here, `EncryptedFileSystem` is equal to 1 on all data nodes, which means that filesystem encryption is enabled for this cluster.

### 25.6.14.2 NDB File System Encryption Implementation

For **NDB** Transparent Data Encryption (TDE), data nodes encrypt user data at rest, with security provided by a password (file system password), which is used to encrypt and decrypt a secrets file on each data node. The secrets file contains a Node Master Key (NMK), a key used later to encrypt the different file types used for persistence. **NDB** TDE encrypts user data files including LCP files, redo log files, tablespace files, and undo log files.

You can use the `ndbxfrm` utility to see whether a file is encrypted, as shown here:

```bash
> ndbxfrm -i ndb_5_fs/LCP/0/T2F0.Data
File=ndb_5_fs/LCP/0/T2F0.Data, compression=no, encryption=yes
> ndbxfrm -i ndb_6_fs/LCP/0/T2F0.Data
File=ndb_6_fs/LCP/0/T2F0.Data, compression=no, encryption=no
```

It is possible to obtain the key from the secrets file using the `ndb_secretsfile_reader` program, like this:

```bash
> ndb_secretsfile_reader --filesystem-password=54kl14 ndb_5_fs/D1/NDBCNTR/S0.sysfile
ndb_secretsfile_reader: WARNING: Using a password on the command line interface can be insecure.
 cac256e182dd7d6be782d999a72f18e864b7b8453cc7fa40bfaf0c40b91122d18
```

The per-node key hierarchy can be represented as follows:

- A user-supplied passphrase (P) is processed by a key-derivation function using a random salt to generate a unique passphrase key (PK).

- The PK (unique to each node) encrypts the data on each node in its own secrets file.

- The data in the secrets file includes a unique, randomly generated Node Master Key (NMK).

- The NMK encyptes (using wrapping) one or more randomly generated data encryption key (DEK) values in the header of each encrypted file (including LCP and TS files, and redo and undo logs).

- Data encryption key values (DEK₀, ..., DEKₙ) are used for encryption of [subsets of] data in each file.

The passphrase indirectly encrypts the secrets file containing the random NMK, which encrypts a portion of the header of each encrypted file on the node. The encrypted file header contains random data keys used for the data in that file.
Encryption is implemented transparently by the NDBFS layer within the data nodes. NDBFS internal client blocks operate on their files as normal; NDBFS wraps the physical file with extra header and footer information supporting encryption, and encrypts and decrypts data as it is read from and written to the file. The wrapped file format is referred to as ndbxfml.

The node password is processed with PBKDF2 and the random salt to encrypt the secrets file, which contains the randomly generated NMK which is used to encrypt the randomly generated data encryption key in each encrypted file.

The work of encryption and decryption is performed in the NDBFS I/O threads (rather than in signal execution threads such as main, tc, ldm, or rep). This is similar to what happens with compressed LCPs and compressed backups, and normally results in increased I/O thread CPU usage; you may wish to adjust ThreadConfig (if in use) with regard to the I/O threads.

25.6.14.3 NDB File System Encryption Limitations

Transparent data encryption in NDB Cluster is subject to the following restrictions and limitations:

- The file system password must be supplied to each individual data node.
- File system password rotation requires an initial rolling restart of the data nodes; this must be performed manually, or by an application external to NDB.
- For a cluster with only a single replica (NoOfReplicas = 1), a full backup and restore is required for file system password rotation.
- Rotation of all data encryption keys requires an initial node restart.

25.6.15 TLS Link Encryption for NDB Cluster

This section discusses the implementation and use of Transport Layer Security (TLS) to secure network communications in MySQL NDB Cluster. Topics covered include keys and certificates, key and certificate life cycles, authentication of certificates, and how these are reflected in the configuration of the cluster, as well as NDB Cluster support for the Internet Public Key Infrastructure (PKI) used to authenticate and encrypt connections between NDB nodes, and between the NDB management server and its clients.

Note

TLS for NDB Cluster on Linux requires compiled-in support for OpenSSL 1.1 or later. For this reason, it is not available for Enterprise Linux 7, which is built with OpenSSL 1.0.

25.6.15.1 Overview of TLS for NDB Cluster

TLS can be used to secure network communications in NDB Cluster 8.3 and later. NDB Transporter connections secured by TLS use TLS mutual authentication, in which each node validates the certificate of its peer. A node certificate can also be bound to a particular hostname; in this case, a peer authorizes the certificate only if the hostname can be verified.

A node's own certificate file contains the entire chain of trust it uses to validate the certificates of its peers. This usually includes only its own certificate and that of the issuing CA, but may include additional CAs. Because an NDB cluster is considered a realm of trust, the CA should be limited in scope to a single cluster.

In order to obtain signed node certificates, it is necessary first to create a Certification Authority (CA). When TLS is deployed, every node has an authentic certificate, which is signed by the CA. Only the administrator (DBA) should have access to the private CA signing key with which valid node certificates are created.
Hostname bindings are created for management and API node certificates by default. Since NDB Cluster data nodes are already subject to hostname checks as part of node ID allocation, the default behavior is to not add an additional hostname check for TLS.

A certificate is no longer valid upon arrival of the expiration date. To minimize the impact of certificate expiration on system availability, a cluster should have several certificates with staggered expiration dates; client certificates should expire earliest, followed by data node certificates, and then by management server certificates. To facilitate staggered expiration, each certificate is associated with a node type; a given node uses keys and certificates of the appropriate type only.

Private keys are created in place; copying of files containing private keys is minimized. Both private keys and certificates are labeled as either active (current) or pending. It is possible to rotate keys to allow for pending keys to replace active keys before the active keys expire.

Due to the potentially large numbers of files involved, NDB follows several naming conventions for files storing keys, signing requests, and certificates. These names are not user configurable, although the directories where these files are stored can be determined by the user.

By default, NDB Cluster CA private keys are protected by a passphrase which must be provided when creating a signed node certificate. Node private keys are stored unencrypted, so that they can be opened automatically at node startup time. Private key files are read-only (Unix file mode 0400).

### 25.6.15.2 Creating a CA and Keys

Create a CA in the CA directory:

```
$> ndb_sign_keys --create-CA --to-dir=CA
Mode of operation: create CA.
This utility will create a cluster CA private key and a public key certificate.

You will be prompted to supply a pass phrase to protect the cluster private key. This security of the cluster depends on this.

Only the database administrator responsible for this cluster should have the pass phrase. Knowing the pass phrase would allow an attacker to gain full access to the database.

The passphrase must be at least 4 characters in length.

Creating CA key file NDB-Cluster-private-key in directory CA.
Enter PEM pass phrase: Verifying - Enter PEM pass phrase:
Creating CA certificate NDB-Cluster-cert in directory CA.
```

```
$> ls -l CA
total 8
-rw-r--r-- 1 mysql mysql 1082 Dec 19 07:32 NDB-Cluster-cert
-r-------- 1 mysql mysql 1854 Dec 19 07:32 NDB-Cluster-private-key
```

Next, create keys for all nodes on this host using the `--create-key` option, like this:

```
$> ndb_sign_keys --ndb-tls-search-path='CA' --create-key -c localhost:1186 --to-dir=keys
Mode of operation: create active keys and certificates.
Enter PEM pass phrase:
Creating active private key in directory keys.
Creating active certificate in directory keys.
Read 5 nodes from cluster configuration.
Found 5 nodes configured to run on this host.
Created 3 keys and 3 certificates.
```

```
--create-key causes ndb_sign_keys to connect to the management server, read the cluster configuration, and then create a full set of keys and certificates for all NDB nodes configured to run on the local host. The cluster management server must be running for this to work. If the management server is not running, ndb_sign_keys can read the cluster configuration file directly using the --
config-file option. ndb_sign_keys can also create a single key-certificate pair for a single node type using --no-config to ignore the cluster configuration and --node-type to specify the node type (one of mgmd, db, or api). In addition, you must either specify a hostname for the certificate with --bound-hostname=host_name, or disable hostname binding by supplying --bind-host=0.

Key signing by a remote host is accomplished by connecting to the CA host using ssh.

### 25.6.15.3 Using TLS Connections

Once you have created a CA and certificate, you can test the availability of the TLS connection to the management server by running the ndb_mgm client with --test-tls, like this:

```
$> ndb_mgm --test-tls
No valid certificate.
```

An appropriate message is generated if the client can connect using TLS. You may need to include other ndb_mgm options such as --ndb-tls-search-path to facilitate the TLS connection, as shown here:

```
$> ndb_mgm --test-tls --ndb-tls-search-path="CA:keys"
Connected to management server at localhost port 1186 (using TLS)
```

If the client connects without using TLS, this is also indicated, similarly to what is shown here:

```
$> ndb_mgm
Connected to management server at localhost port 1186 (using cleartext)
```

You can cause the cluster to use the CA and certificates created with ndb_sign_keys by performing a rolling restart of the cluster, beginning with the management nodes, which should be restarted using the --ndb-tls-search-path option. After this, restart the data nodes, again using --ndb-tls-search-path. --ndb-tls-search-path is also supported for mysqld run as a cluster API node.

For TLS to function, every node connecting to the cluster must have a valid certificate and key. This includes data nodes, API nodes, and utility programs. The same certificate and key files can be used by more than one node.

Data nodes log the TLS connection and include the full path to the certificate file used, as shown here:

```
$> ndb_mtd --c localhost:1186 --ndb-tls-search-path='CA:keys'
2023-12-19 12:02:15 [ndbd] INFO -- NDB TLS 1.3 available using certificate file 'keys/ndb-data-node-cert'
2023-12-19 12:02:15 [ndbd] INFO -- Angel connected to 'localhost:1186'
2023-12-19 12:02:15 [ndbd] INFO -- Angel allocated nodeid: 5
```

You can verify that cluster nodes are using TLS to connect by checking the output of the TLS INFO command in the ndb_mgm client, like this:

```
$> ndb_mgm --ndb-tls-search-path="CA:keys"
-- NDB Cluster -- Management Client --
ndb_mgm> TLS INFO
Connected to management server at localhost port 1186 (using TLS)
```

Main interactive connection is using TLS
Event listener connection is using TLS
Server reports 6 TLS connections.

```

Server statistics since restart
Total accepted connections:        32
Total connections upgraded to TLS: 8
Current connections:               6
Current connections using TLS:     6
Authorization failures:            0
ndb_mgm>

If Current connections and Current connections using TLS are the same, this means that all cluster connections are using TLS.

Once you have established TLS connections for all nodes, you should make TLS a strict requirement. For clients, you can do this by setting `ndb-mgm-tls=strict` in the `my.cnf` file on each cluster host. Enforce the TLS requirement on the management server by setting `RequireTls=true` in the `[mgm default]` section of the cluster `config.ini` file, then performing a rolling restart of the cluster so that this change takes effect. Do this for the data nodes as well, by setting `RequireTls=true` in the `[ndbd default]` section of the configuration file; after this, perform a second rolling restart of the cluster to make the changes take effect on the data nodes. Start `ndb_mgmd` with the `--reload` and `--config-file` options both times to ensure that each of the two configuration file changes is read by the management server.

To replace a private key, use `ndb_sign_keys --create-key` to create the new key and certificate, with the `--node-id` and `--node-type_options` if and as necessary to limit the replacement to a single node ID, node type, or both. If the tool finds existing key and certificate files, it renames them to reflect their retired status, and saves the newly created key and certificate as active files; the new files are used the next time that the node is restarted.

To replace a certificate without replacing the private key, use `ndb_sign_keys` without supplying the `--create-key` option. This creates a new certificate for the existing key (without replacing the key), and retires the old certificate.

Remote key siging is also supported by `ndb_sign_keys`. Using SSH, the `--remote-CA-host` option supplies the SSH address of the CA host in `user@host` format. By default, the local `ndb_sign_keys` process uses the system `ssh` utility and address to run `ndb_sign_keys` on the remote host with the correct options to perform the desired signing. Alternately, if `--remote-openssl=true`, `openssl` rather than `ndb_sign_keys` is used on the remote host.

When using remote signing, the data sent over the network is a PKCS#10 signing request, and not the private key, which never leaves the local host.

25.6.16 NDB API Statistics Counters and Variables
A number of types of statistical counters relating to actions performed by or affecting Ndb objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by NDBCLUSTER. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. mysqld exposes these counters as system status variables; their values can be read in the output of \texttt{SHOW STATUS}, or by querying the Performance Schema session_status or global_status table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following \texttt{SHOW STATUS} statement:

```sql
mysql> \texttt{SHOW STATUS LIKE 'ndb_api%';}
```

</tbody>
</table>
Each Ndb object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one Ndb object concurrently, it is also possible to obtain a summed view of counters from all Ndb objects belonging to a given Ndb_cluster_connection.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. This is in spite of the fact that their values can be obtained as either session or global status variables in the mysql client. This means that specifying the SESSION or GLOBAL keyword with SHOW STATUS has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the session_status or the global_status table.

• Session counters (session specific)

Session counters relate to the Ndb objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "_session variables", with a leading underscore.

• Replica counters (global)

This set of counters relates to the Ndb objects used by the replica SQL thread, if any. If this mysqld does not act as a replica, or does not use NDB tables, then all of these counts are 0.

We refer to the related status variables as "_replica variables" (with a leading underscore).

• Injector counters (global)

Injector counters relate to the Ndb object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, mysqld processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

We refer to the status variables that correspond to NDB API injector counters as "_injector variables" (with a leading underscore).

• Server (Global) counters (global)

This set of counters relates to all Ndb objects currently used by this mysqld. This includes all MySQL client applications, the replica SQL thread (if any), the binary log injector, and the NDB utility thread.
We refer to the status variables that correspond to these counters as “global variables” or “mysqld-level variables”.

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `replica`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
+----------------------------------------------+---------+
| Variable_name                                | Value   |
+----------------------------------------------+---------+
| Ndb_api_wait_exec_complete_count_session     | 0       |
| Ndb_api_wait_scan_result_count_session       | 3       |
| Ndb_api_wait_meta_request_count_session      | 6       |
| Ndb_api_wait_nanoseconds_count_session       | 2022486 |
| Ndb_api_bytes_sent_count_session             | 268     |
| Ndb_api_bytes_received_count_session         | 10332   |
| Ndb_api_trans_start_count_session            | 1       |
| Ndb_api_trans_commit_count_session           | 0       |
| Ndb_api_trans_abort_count_session            | 0       |
| Ndb_api_trans_close_count_session            | 1       |
| Ndb_api_pk_op_count_session                  | 0       |
| Ndb_api_uk_op_count_session                  | 0       |
| Ndb_api_table_scan_count_session             | 1       |
| Ndb_api_range_scan_count_session             | 0       |
| Ndb_api_pruned_scan_count_session            | 0       |
| Ndb_api_scan_batch_count_session             | 2       |
| Ndb_api_read_row_count_session               | 2       |
| Ndb_api_trans_local_read_row_count_session   | 2       |
| Ndb_api_adaptive_send_forced_count_session   | 1       |
| Ndb_api_adaptive_send_unforced_count_session | 0       |
| Ndb_api_adaptive_send_deferred_count_session | 0       |
+----------------------------------------------+---------+
21 rows in set (0.00 sec)
```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `count`, like this:

```
mysql> SELECT * FROM performance_schema.session_status
    -> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+------------------------------------+----------------+
| VARIABLE_NAME                      | VARIABLE_VALUE |
+------------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT   | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT     | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT    | 28             |
| NDB_API_WAIT_NANOS_COUNT           | 53756398       |
| NDB_API_BYTES_SENT_COUNT           | 1060           |
| NDB_APIBYTES_RECEIVED_COUNT        | 9724           |
| NDB_API_TRANS_START_COUNT          | 3              |
| NDB_API_TRANS_COMMIT_COUNT         | 2              |
| NDB_API_TRANS_ABORT_COUNT          | 0              |
| NDB_API_TRANS_CLOSE_COUNT          | 3              |
| NDB_API_PK_OP_COUNT                | 2              |
| NDB_APIUK_OP_COUNT                 | 0              |
| NDB_API_TABLE_SCAN_COUNT           | 1              |
| NDB_API_RANGE_SCAN_COUNT           | 0              |
| NDB_API_PRUNED_SCAN_COUNT          | 0              |
| NDB_API_SCAN_BATCH_COUNT           | 0              |
| NDB_API_READ_ROW_COUNT             | 2              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2              |
| NDB_API_EVENT_DATA_COUNT           | 0              |
| NDB_API_EVENT_NONDATA_COUNT        | 0              |
| NDB_API_EVENT_BYTES_COUNT          | 0              |
+------------------------------------+----------------+
21 rows in set (0.09 sec)
```
Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```sql
mysql> SHOW STATUS LIKE 'ndb_api%event%';
+--------------------------------------+-------+
| Variable_name                        | Value |
+--------------------------------------+-------+
| Ndb_api_event_data_count_injector    | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector   | 0     |
| Ndb_api_event_data_count             | 0     |
| Ndb_api_event_nondata_count          | 0     |
| Ndb_api_event_bytes_count            | 0     |
+--------------------------------------+-------+
6 rows in set (0.00 sec)
```

_Injector_ status variables are not implemented for any other NDB API counters, as shown here:

```sql
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+--------------------------------------+-------+
| Variable_name                        | Value |
+--------------------------------------+-------+
| Ndb_api_event_data_count_injector    | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector   | 0     |
+--------------------------------------+-------+
3 rows in set (0.00 sec)
```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

**Table 25.39 NDB API statistics counters**

<table>
<thead>
<tr>
<th>Counter Name</th>
<th>Description</th>
<th>Status Variables (by statistic type):</th>
</tr>
</thead>
</table>
| WaitExecCompleteCount       | Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all `execute()` calls as well as implicit executes for blob operations and auto-increment not visible to clients. | • Ndb_api_wait_exec_complete_count_session  
                                |                                | • Ndb_api_wait_exec_complete_count_replica  
                                |                                | • [none]  
                                |                                | • Ndb_api_wait_exec_complete_count  |
| WaitScanResultCount         | Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close. | • Ndb_api_wait_scan_result_count_session  
                                |                                | • Ndb_api_wait_scan_result_count_replica  
                                |                                | • [none]  
                                |                                | • Ndb_api_wait_scan_result_count  |
| WaitMetaRequestCount        | Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL | • Ndb_api_wait_meta_request_count_session  
                                |                                | • Ndb_api_wait_meta_request_count_replica  
                                |                                | • [none]

<td>- Ndb_api_event_bytes_count</td>
</tr>
</tbody>
</table>

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```sql
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+------------------------------------+-------+
| Variable_name                      | Value |
+------------------------------------+-------+
| Ndb_api_trans_commit_count_session | 1     |
| Ndb_api_trans_commit_count_slave   | 0     |
| Ndb_api_trans_commit_count         | 2     |
+------------------------------------+-------+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing...
the statement. In this example, after getting the initial values from SHOW STATUS, we create in the test database an NDB table, named t, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+--------+
| Variable_name                              | Value  |
+--------------------------------------------+--------+
| Ndb_api_wait_exec_complete_count_session   | 2      |
| Ndb_api_wait_scan_result_count_session     | 0      |
| Ndb_api_wait_meta_request_count_session    | 3      |
| Ndb_api_wait_nanos_count_session           | 820705 |
| Ndb_api_bytes_sent_count_session           | 132    |
| Ndb_api_bytes_received_count_session       | 372    |
| Ndb_api_trans_start_count_session          | 1      |
| Ndb_api_trans_commit_count_session         | 1      |
| Ndb_api_trans_abort_count_session          | 0      |
| Ndb_api_trans_close_count_session          | 1      |
| Ndb_api_pk_op_count_session                | 1      |
| Ndb_api_uk_op_count_session                | 0      |
| Ndb_api_table_scan_count_session           | 0      |
| Ndb_api_range_scan_count_session           | 0      |
| Ndb_api_pruned_scan_count_session          | 0      |
| Ndb_api_scan_batch_count_session           | 0      |
| Ndb_api_read_row_count_session             | 1      |
| Ndb_api_trans_local_read_row_count_session | 1      |
+--------------------------------------------+--------+
18 rows in set (0.00 sec)
```

Now you can execute a new SHOW STATUS statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into t:

```
Insert the row, then run the same SHOW STATUS statement used in the previous example, as shown here:
```

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+-----------+
| Variable_name                              | Value     |
+--------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session   | 8         |
| Ndb_api_wait_scan_result_count_session     | 0         |
| Ndb_api_wait_meta_request_count_session    | 17        |
| Ndb_api_wait_nanos_count_session           | 706871709 |
| Ndb_api_bytes_sent_count_session           | 2376      |
| Ndb_api_bytes_received_count_session       | 3844      |
| Ndb_api_trans_start_count_session          | 4         |
| Ndb_api_trans_commit_count_session         | 4         |
| Ndb_api_trans_abort_count_session          | 0         |
| Ndb_api_trans_close_count_session          | 4         |
| Ndb_api_pk_op_count_session                | 6         |
| Ndb_api_uk_op_count_session                | 0         |
| Ndb_api_table_scan_count_session           | 0         |
| Ndb_api_range_scan_count_session           | 0         |
| Ndb_api_pruned_scan_count_session          | 0         |
| Ndb_api_scan_batch_count_session           | 0         |
| Ndb_api_read_row_count_session             | 2         |
| Ndb_api_trans_local_read_row_count_session | 1         |
+--------------------------------------------+-----------+
18 rows in set (0.00 sec)
```
We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the NDB storage engine.

- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` (707370418 - 706871709 = 498709 ns or roughly 0.0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_replica`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

### 25.6.17 ndbinfo: The NDB Cluster Information Database

`ndbinfo` is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+----------------+--------+--------------------+---------+---------+
| Name           | Status | Type               | Library | License |
+----------------+--------+--------------------+---------+---------+
| binlog         | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
```
You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the `Engine` column and `YES` in the `Support` column, as shown here (emphasized text):

```
mysql> SHOW ENGINES
*************************** 1. row ***************************
Engine: MEMORY
Support: YES
Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
XA: NO
Savepoints: NO
*************************** 2. row ***************************
Engine: InnoDB
Support: DEFAULT
Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
XA: YES
Savepoints: YES
*************************** 3. row ***************************
Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
Transactions: NO
```

```

| 10 rows in set (0.01 sec)       |

If ndbinfo support is enabled, then you can access ndbinfo using SQL statements in mysql or another MySQL client. For example, you can see ndbinfo listed in the output of SHOW DATABASES, as shown here (emphasized text):

```sql
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| performance_schema |
| sys                |
+--------------------+
5 rows in set (0.04 sec)
```

If the mysqld process was not started with the --ndbcluster option, ndbinfo is not available and is not displayed by SHOW DATABASES. If mysqld was formerly connected to an NDB Cluster but the
cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), ndbinfo and its tables remain visible, but an attempt to access any tables (other than blocks or config_params) fails with Got error 157 'Connection to NDB failed' from NDBINFO.

With the exception of the blocks and config_params tables, what we refer to as ndbinfo "tables" are actually views generated from internal NDB tables not normally visible to the MySQL Server. You can make these tables visible by setting the ndbinfo_show_hidden system variable to ON (or 1), but this is normally not necessary.

All ndbinfo tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on ndbinfo tables; so joining large ndbinfo tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a WHERE clause.

ndbinfo tables are not included in the query cache. (Bug #59831)

You can select the ndbinfo database with a USE statement, and then issue a SHOW TABLES statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+---------------------------------+
| Tables_in_ndbinfo               |
+---------------------------------+
| arbitrator_validity_detail      |
| arbitrator_validity_summary     |
| backup_id                       |
| blobs                           |
| blocks                          |
| certificates                    |
| cluster_locks                   |
| cluster_operations              |
| cluster_transactions            |
| config_nodes                    |
| config_params                   |
| config_values                   |
| counters                        |
| cpudata                         |
| cpudata_lsec                    |
| cpudata_20sec                   |
| cpudata_50ms                    |
| cpuninfo                        |
| cpustat                         |
| cpustat_lsec                    |
| cpustat_20sec                   |
| cpustat_50ms                    |
| dict_obj_info                   |
| dict_obj_tree                   |
| dict_obj_types                  |
| dictionary_columns              |
| dictionary_tables               |
| disk_write_speed_aggregate      |
| disk_write_speed_aggregate_node |
| disk_write_speed_base           |
| diskpagebuffer                  |
| diskstat                        |
| diskstats_lsec                  |
| error_messages                  |
| events                          |
| files                           |
| foreign_keys                    |
| hash_maps                       |
```
All ndbinfo tables use the NDB storage engine; however, an ndbinfo entry still appears in the output of `SHOW ENGINES` and `SHOW PLUGINS` as described previously.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```sql
mysql> SELECT * FROM memoryusage;
```

```sql
+---------+---------------------+--------+------------+------------+-------------+
| node_id | memory_type         | used   | used_pages | total      | total_pages |
+---------+---------------------+--------+------------+------------+-------------+
|       5 | Data memory         | 425984 |         13 | 2147483648 |       65536 |
|       5 | Long message buffer | 393216 |       1536 |   67108864 |      262144 |
|       6 | Data memory         | 425984 |         13 | 2147483648 |       65536 |
|       6 | Long message buffer | 393216 |       1536 |   67108864 |      262144 |
|       7 | Data memory         | 425984 |         13 | 2147483648 |       65536 |
|       7 | Long message buffer | 393216 |       1536 |   67108864 |      262144 |
|       8 | Data memory         | 425984 |         13 | 2147483648 |       65536 |
|       8 | Long message buffer | 393216 |       1536 |   67108864 |      262144 |
+---------+---------------------+--------+------------+------------+-------------+
8 rows in set (0.09 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```sql
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
    > FROM memoryusage
    > WHERE memory_type = 'Data memory';
```

```sql
+-----------------------------+
<table>
<thead>
<tr>
<th>Data Memory Used, All Nodes</th>
</tr>
</thead>
<tbody>
<tr>
<td>6460</td>
</tr>
</tbody>
</table>
+-----------------------------+
1 row in set (0.09 sec)
```

```sql
mysql> SELECT SUM(used) as 'Long Message Buffer Used, All Nodes'
    > FROM memoryusage
    > WHERE memory_type = 'Long message buffer';
```

```sql
+-------------------------------------+
<table>
<thead>
<tr>
<th>Long Message Buffer Used, All Nodes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1179648</td>
</tr>
</tbody>
</table>
+-------------------------------------+
```
ndbinfo: The NDB Cluster Information Database

ndbinfo table and column names are case-sensitive (as is the name of the ndbinfo database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```sql
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       5 |  17707 | STARTED |           0 |                 1 |
|       6 |  17706 | STARTED |           0 |                 1 |
|       7 |  17705 | STARTED |           0 |                 1 |
|       8 |  17704 | STARTED |           0 |                 1 |
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.06 sec)
```

```sql
mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

`mysqldump` ignores the ndbinfo database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

NDB Cluster also maintains tables in the INFORMATION_SCHEMA information database, including the FILES table which contains information about files used for NDB Cluster Disk Data storage, and the ndb_transid_mysql_connection_map table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or Section 25.6.18, "INFORMATION_SCHEMA Tables for NDB Cluster".

### 25.6.17.1 The ndbinfo arbitrator_validity_detail Table

The arbitrator_validity_detail table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the membership table.

The arbitrator_validity_detail table contains the following columns:

- **node_id**
  
  This node's node ID

- **arbitrator**
  
  Node ID of arbitrator

- **arb_ticket**
  
  Internal identifier used to track arbitration

- **arb_connected**
  
  Whether this node is connected to the arbitrator; either of **Yes** or **No**

- **arb_state**
  
  Arbitration state

#### Notes

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same arbitrator and arb_ticket values as well as the same arb_state value. Possible arb_state values are ARBIT_NULL, ARBIT_INIT, ARBIT_FIND,
25.6.17.2 The ndbinfo arbitrator_validity_summary Table

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The `arbitrator_validity_summary` table contains the following columns:

- **arbitrator**: Node ID of arbitrator
- **arb_ticket**: Internal identifier used to track arbitration
- **arb_connected**: Whether this arbitrator is connected to the cluster
- **consensus_count**: Number of data nodes that see this node as arbitrator; either of Yes or No

Notes

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The **arbitrator** column shows the arbitrator's node ID.

**arb_ticket** is the internal identifier used by this arbitrator.

**arb_connected** shows whether this node is connected to the cluster as an arbitrator.

25.6.17.3 The ndbinfo backup_id Table

This table provides a way to find the ID of the backup started most recently for this cluster.

The **backup_id** table contains a single column **id**, which corresponds to a backup ID taken using the `ndb_mgm` client `START BACKUP` command. This table contains a single row.

Example: Assume the following sequence of `START BACKUP` commands issued in the NDB management client, with no other backups taken since the cluster was first started:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 5: Backup 1 started from node 50
Node 5: Backup 1 started from node 50 completed
StartGCP: 27894 StopGCP: 27897
#Records: 2057 #LogRecords: 0
Data: 51580 bytes Log: 0 bytes
ndb_mgm> START BACKUP 5
Waiting for completed, this may take several minutes
Node 5: Backup 5 started from node 50
Node 5: Backup 5 started from node 50 completed
StartGCP: 27905 StopGCP: 27908
#Records: 2057 #LogRecords: 0
Data: 51580 bytes Log: 0 bytes
```
After this, the backup_id table contains the single row shown here, using the mysql client:

mysql> USE ndbinf;  
Database changed
mysql> SELECT * FROM backup_id;
+----+
<table>
<thead>
<tr>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
+----+
1 row in set (0.00 sec)

If no backups can be found, the table contains a single row with 0 as the id value.

25.6.17.4 The ndbinf blobs Table

This table provides about blob values stored in NDB. The blobs table has the columns listed here:

- **table_id**
  Unique ID of the table containing the column

- **database_name**
  Name of the database in which this table resides

- **table_name**
  Name of the table

- **column_id**
  The column's unique ID within the table

- **column_name**
  Name of the column

- **inline_size**
  Inline size of the column

- **part_size**
  Part size of the column

- **stripe_size**
  Stripe size of the column
• **blob_table_name**

Name of the blob table containing this column's blob data, if any

Rows exist in this table for those NDB table columns that store BLOB, TEXT values taking up more than 255 bytes and thus require the use of a blob table. Parts of JSON values exceeding 4000 bytes in size are also stored in this table. For more information about how NDB Cluster stores columns of such types, see String Type Storage Requirements.

The part and inline sizes of NDB blob columns can be set using CREATE TABLE and ALTER TABLE statements containing NDB table column comments (see NDB_COLUMN Options); this can also be done in NDB API applications (see Column::setPartSize() and setInlineSize()).

### 25.6.17.5 The ndbinfo blocks Table

The **blocks** table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other ndbinfo tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The **blocks** table contains the following columns:

- **block_number**
  Block number
- **block_name**
  Block name

**Notes**

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

### 25.6.17.6 The ndbinfo certificates Table

The **certificates** table provides information about the certificates used by nodes connecting with TLS link encryption (see Section 25.6.15, “TLS Link Encryption for NDB Cluster”).

The **certificates** table contains the following columns:

- **Node_id**
  ID of the node where this certificate is found
- **Name**
  Certificate name
- **Expires**
  Expiration date, in **mm-nnn-yyyy** format (for example, **18-Dec-2023**).
- **Serial**
  Serial number

### 25.6.17.7 The ndbinfo cluster_locks Table

The **cluster_locks** table provides information about current lock requests holding and waiting for locks on NDB tables in an NDB Cluster, and is intended as a companion table to
Cluster Operations. Information obtain from the cluster_locks table may be useful in investigating stalls and deadlocks.

The cluster_locks table contains the following columns:

- **node_id**
  ID of reporting node

- **block_instance**
  ID of reporting LDM instance

- **tableid**
  ID of table containing this row

- **fragmentid**
  ID of fragment containing locked row

- **rowid**
  ID of locked row

- **transid**
  Transaction ID

- **mode**
  Lock request mode

- **state**
  Lock state

- **detail**
  Whether this is first holding lock in row lock queue

- **op**
  Operation type

- **duration_millis**
  Milliseconds spent waiting or holding lock

- **lock_num**
  ID of lock object

- **waiting_for**
  Waiting for lock with this ID

Notes

The table ID (tableid column) is assigned internally, and is the same as that used in other ndbinfo tables. It is also shown in the output of ndb_show_tables.

The transaction ID (transid column) is the identifier generated by the NDB API for the transaction requesting or holding the current lock.
The **mode** column shows the lock mode; this is always one of **S** (indicating a shared lock) or **X** (an exclusive lock). If a transaction holds an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The **state** column shows the lock state. Its value is always one of **H** (holding) or **W** (waiting). A waiting lock request waits for a lock held by a different transaction.

When the **detail** column contains a * (asterisk character), this means that this lock is the first holding lock in the affected row's lock queue; otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The **op** column shows the type of operation requesting the lock. This is always one of the values **READ**, **INSERT**, **UPDATE**, **DELETE**, **SCAN**, or **REFRESH**.

The **duration_millis** column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (**lockid** column) is unique to this node and block instance.

The lock state is shown in the **lock_state** column; if this is **W**, the lock is waiting to be granted, and the **waiting_for** column shows the lock ID of the lock object this request is waiting for. Otherwise, the **waiting_for** column is empty. **waiting_for** can refer only to locks on the same row, as identified by **node_id**, **block_instance**, **tableid**, **fragmentid**, and **rowid**.

### 25.6.17.8 The ndbinfo cluster_operations Table

The **cluster_operations** table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The **cluster_operations** table contains the following columns:

- **node_id**
  
  Node ID of reporting LQH block

- **block_instance**
  
  LQH block instance

- **transid**
  
  Transaction ID

- **operation_type**
  
  Operation type (see text for possible values)

- **state**
  
  Operation state (see text for possible values)

- **tableid**
  
  Table ID

- **fragmentid**
  
  Fragment ID

- **client_node_id**
  
  Client node ID
- **client_block_ref**
  Client block reference

- **tc_node_id**
  Transaction coordinator node ID

- **tc_block_no**
  Transaction coordinator block number

- **tc_block_instance**
  Transaction coordinator block instance

**Notes**

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUE`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide, respectively, the `DBLQH` and `DBTC` block instance numbers. You can use these along with the block names to obtain information about specific threads from the `threadblocks` table.

**25.6.17.9 The ndbinfo cluster_transactions Table**

The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The `cluster_transactions` table contains the following columns:

- **node_id**
  Node ID of transaction coordinator

- **block_instance**
TC block instance

- **transid**
  Transaction ID

- **state**
  Operation state (see text for possible values)

- **count_operations**
  Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)

- **outstanding_operations**
  Operations still being executed in local data management blocks

- **inactive_seconds**
  Time spent waiting for API

- **client_node_id**
  Client node ID

- **client_block_ref**
  Client block reference

**Notes**

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `state` column can have any one of the values `CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMMITTING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `tc_block_instance` column provides the DBTC block instance number. You can use this along with the block name to obtain information about specific threads from the `threadblocks` table.

### 25.6.17.10 The ndbinfo config_nodes Table

The `config_nodes` table shows nodes configured in an NDB Cluster `config.ini` file. For each node, the table displays a row containing the node ID, the type of node (management node, data node, or API node), and the name or IP address of the host on which the node is configured to run.
This table does not indicate whether a given node is actually running, or whether it is currently connected to the cluster. Information about nodes connected to an NDB Cluster can be obtained from the nodes and processes table.

The config_nodes table contains the following columns:

- **node_id**
  The node's ID
- **node_type**
  The type of node
- **node_hostname**
  The name or IP address of the host on which the node resides

**Notes**

The node_id column shows the node ID used in the config.ini file for this node; if none is specified, the node ID that would be assigned automatically to this node is displayed.

The node_type column displays one of the following three values:

- **MGM**: Management node.
- **NDB**: Data node.
- **API**: API node; this includes SQL nodes.

The node_hostname column shows the node host as specified in the config.ini file. This can be empty for an API node, if HostName has not been set in the cluster configuration file. If HostName has not been set for a data node in the configuration file, localhost is used here. localhost is also used if HostName has not been specified for a management node.

### 25.6.17.11 The ndbinfo config_params Table

The config_params table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters. This table can also be used in conjunction with the config_values table for obtaining realtime information about node configuration parameters.

The config_params table contains the following columns:

- **param_number**
  The parameter's internal ID number
- **param_name**
  The name of the parameter
- **param_description**
  A brief description of the parameter
- **param_type**
  The parameter's data type
- **param_default**
 
The parameter’s default value, if any

- **param_min**

The parameter’s maximum value, if any

- **param_max**

The parameter’s minimum value, if any

- **param_mandatory**

This is 1 if the parameter is required, otherwise 0

- **param_status**

Currently unused

**Notes**

This table is read-only.

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

### 25.6.17.12 The ndbinfo config_values Table

The `config_values` table provides information about the current state of node configuration parameter values. Each row in the table corresponds to the current value of a parameter on a given node.

The `config_values` table contains the following columns:

- **node_id**

  ID of the node in the cluster

- **config_param**

  The parameter’s internal ID number

- **config_value**

  Current value of the parameter

**Notes**

This table’s `config_param` column and the `config_params` table’s `param_number` column use the same parameter identifiers. By joining the two tables on these columns, you can obtain detailed information about desired node configuration parameters. The query shown here provides the current values for all parameters on each data node in the cluster, ordered by node ID and parameter name:

```sql
SELECT v.node_id AS 'Node Id',
       p.param_name AS 'Parameter',
       v.config_value AS 'Value'
FROM config_values v
JOIN config_params p
ON v.config_param = p.param_number
WHERE p.param_name NOT LIKE '\\_%'
ORDER BY v.node_id, p.param_name;
```

Partial output from the previous query when run on a small example cluster used for simple testing:
The WHERE clause filters out parameters whose names begin with a double underscore (_ _): these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

You can obtain output that is more specific, more detailed, or both by issuing the proper queries. This example provides all types of available information about the NodeId, NoOfReplicas, HostName, DataMemory, IndexMemory, and TotalSendBufferMemory parameters as currently set for all data nodes in the cluster:

```
SELECT  p.param_name AS Name,
        v.node_id AS Node,
        p.param_type AS Type,
        p.param_default AS 'Default',
        p.param_min AS Minimum,
        p.param_max AS Maximum,
        CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
        v.config_value AS Current
FROM    config_params p
JOIN    config_values v
        ON p.param_number = v.config_param
WHERE   p.param_name
        IN ('NodeId', 'NoOfReplicas', 'HostName',
            'DataMemory', 'IndexMemory', 'TotalSendBufferMemory')
```

The output from this query when run on a small NDB Cluster with 2 data nodes used for simple testing is shown here:

```
 *********************** 1. row ***********************
 Name: NodeId
 Node: 2
 Type: unsigned
 Default: 0
 Minimum: 1
 Maximum: 144
 Required: Y
 Current: 2

 *********************** 2. row ***********************
 Name: HostName
 Node: 2
 Type: string
 Default: localhost
 Minimum: 
 Maximum: 
 Required: N
 Current: 127.0.0.1

 *********************** 3. row ***********************
 Name: TotalSendBufferMemory
 Node: 2
```

The WHERE clause filters out parameters whose names begin with a double underscore (_ _): these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

</tbody>
</table>

10 rows in set (0.01 sec)
The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The `counters` table contains the following columns:

- **node_id**
  The data node ID

- **block_name**
  Name of the associated NDB kernel block (see NDB Kernel Blocks).

- **block_instance**
  Block instance

- **counter_id**
  The counter’s internal ID number; normally an integer between 1 and 10, inclusive.

- **counter_name**
  The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.

- **val**
  The counter’s value

**Notes**

Each counter is associated with a particular NDB kernel block.

The **OPERATIONS** counter is associated with the DBLQH (local query handler) kernel block. A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in DBLQH per operation in DBTC. For writes, there is one operation counted per fragment replica.

**LOCAL_WRITES** and **LOCAL_READS** are primary-key operations using a transaction coordinator in a node that also holds the primary fragment replica of the record.

The **READS** counter includes all reads. **LOCAL_READS** includes only those reads of the primary fragment replica on the same node as this transaction coordinator. **SIMPLE_READS** includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once DBTC has routed them to the relevant LQH block, it holds no state for them.

**ATTRINFO** keeps a count of the number of times an interpreted program is sent to the data node. See NDB Protocol Messages, for more information about ATTRINFO messages in the NDB kernel.

The block_name and block_instance columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the threadblocks table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- **LQHKEY_OVERLOAD**: Number of primary key requests rejected at the LQH block instance due to transporter overload
- **LQHKEY_OVERLOAD_TC**: Count of instances of LQHKEY_OVERLOAD where the TC node transporter was overloaded
- **LQHKEY_OVERLOAD_READER**: Count of instances of LQHKEY_OVERLOAD where the API reader (reads only) node was overloaded.
- **LQHKEY_OVERLOAD_NODE_PEER**: Count of instances of LQHKEY_OVERLOAD where the next backup data node (writes only) was overloaded.
- **LQHKEY_OVERLOAD_SUBSCRIBER**: Count of instances of LQHKEY_OVERLOAD where a event subscriber (writes only) was overloaded.
- **LQHSCAN_SLOWDOWNS**: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

### 25.6.17.14 The ndbinfo cpudata Table

The cpudata table provides data about CPU usage during the last second.

The cpustat table contains the following columns:

- **node_id**: Node ID
- **cpu_no**: CPU ID
- **cpu_online**: 1 if the CPU is currently online, otherwise 0
- **cpu_userspace_time**: CPU time spent in userspace
- **cpu_idle_time**: CPU time spent idle
- **cpu_system_time**: CPU time spent in system time
- **cpu_interrupt_time**: CPU time spent handling interrupts (hardware and software)
- **cpu_exec_vm_time**: CPU time spent in virtual machine execution
Notes

The `cpudata` table is available only on Linux and Solaris operating systems.

25.6.17.15 The ndbinfo cpudata_1sec Table

The `cpudata_1sec` table provides data about CPU usage per second over the last 20 seconds.

The `cpustat` table contains the following columns:

- `node_id`  
  Node ID
- `measurement_id`  
  Measurement sequence ID; later measurements have lower IDs
- `cpu_no`  
  CPU ID
- `cpu_online`  
  1 if the CPU is currently online, otherwise 0
- `cpu_userspace_time`  
  CPU time spent in userspace
- `cpu_idle_time`  
  CPU time spent idle
- `cpu_system_time`  
  CPU time spent in system time
- `cpu_interrupt_time`  
  CPU time spent handling interrupts (hardware and software)
- `cpu_exec_vm_time`  
  CPU time spent in virtual machine execution
- `elapsed_time`  
  Time in microseconds used for this measurement

Notes

The `cpudata_1sec` table is available only on Linux and Solaris operating systems.

25.6.17.16 The ndbinfo cpudata_20sec Table

The `cpudata_20sec` table provides data about CPU usage per 20-second interval over the last 400 seconds.

The `cpustat` table contains the following columns:

- `node_id`  
  Node ID
ndbinfo: The NDB Cluster Information Database

- **measurement_id**
  Measurement sequence ID; later measurements have lower IDs

- **cpu_no**
  CPU ID

- **cpu_online**
  1 if the CPU is currently online, otherwise 0

- **cpu_userspace_time**
  CPU time spent in userspace

- **cpu_idle_time**
  CPU time spent idle

- **cpu_system_time**
  CPU time spent in system time

- **cpu_interrupt_time**
  CPU time spent handling interrupts (hardware and software)

- **cpu_exec_vm_time**
  CPU time spent in virtual machine execution

- **elapsed_time**
  Time in microseconds used for this measurement

**Notes**

The cpudata_20sec table is available only on Linux and Solaris operating systems.

### 25.6.17.17 The ndbinfo cpudata_50ms Table

The cpudata_50ms table provides data about CPU usage per 50-millisecond interval over the last second.

The cpustat table contains the following columns:

- **node_id**
  Node ID

- **measurement_id**
  Measurement sequence ID; later measurements have lower IDs

- **cpu_no**
  CPU ID

- **cpu_online**
  1 if the CPU is currently online, otherwise 0

- **cpu_userspace_time**
CPU time spent in userspace

• **cpu_idle_time**

CPU time spent idle

• **cpu_system_time**

CPU time spent in system time

• **cpu_interrupt_time**

CPU time spent handling interrupts (hardware and software)

• **cpu_exec_vm_time**

CPU time spent in virtual machine execution

• **elapsed_time**

Time in microseconds used for this measurement

**Notes**

The `cpudata_50ms` table is available only on Linux and Solaris operating systems.

### 25.6.17.18 The ndbinfo cpuinfo Table

The `cpuinfo` table provides information about the CPU on which a given data node executes.

The `cpuinfo` table contains the following columns:

• **node_id**
  
  Node ID

• **cpu_no**
  
  CPU ID

• **cpu_online**
  
  1 if the CPU is online, otherwise 0

• **core_id**
  
  CPU core ID

• **socket_id**
  
  CPU socket ID

**Notes**

The `cpuinfo` table is available on all operating systems supported by NDB, with the exception of MacOS and FreeBSD.

### 25.6.17.19 The ndbinfo cpustat Table

The `cpustat` table provides per-thread CPU statistics gathered each second, for each thread running in the NDB kernel.
The `cpustat` table contains the following columns:

- **node_id**
  ID of the node where the thread is running

- **thr_no**
  Thread ID (specific to this node)

- **OS_user**
  OS user time

- **OS_system**
  OS system time

- **OS_idle**
  OS idle time

- **thread_exec**
  Thread execution time

- **thread_sleeping**
  Thread sleep time

- **thread_spinning**
  Thread spin time

- **thread_send**
  Thread send time

- **thread_buffer_full**
  Thread buffer full time

- **elapsed_time**
  Elapsed time

### 25.6.17.20 The ndbinfo `cpustat_50ms` Table

The `cpustat_50ms` table provides raw, per-thread CPU data obtained each 50 milliseconds for each thread running in the NDB kernel.

Like `cpustat_1sec` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_50ms` provides 1 second of history.

The `cpustat_50ms` table contains the following columns:

- **node_id**
  ID of the node where the thread is running

- **thr_no**
  Thread ID (specific to this node)
ndbinfo: The NDB Cluster Information Database

- **OS_user_time**
  OS user time
- **OS_system_time**
  OS system time
- **OS_idle_time**
  OS idle time
- **exec_time**
  Thread execution time
- **sleep_time**
  Thread sleep time
- **spin_time**
  Thread spin time
- **send_time**
  Thread send time
- **buffer_full_time**
  Thread buffer full time
- **elapsed_time**
  Elapsed time

### 25.6.17.21 The ndbinfo cpustat_1sec Table

The `cpustat-1sec` table provides raw, per-thread CPU data obtained each second for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_1sec` provides 20 seconds of history.

The `cpustat_1sec` table contains the following columns:

- **node_id**
  ID of the node where the thread is running
- **thr_no**
  Thread ID (specific to this node)
- **OS_user_time**
  OS user time
- **OS_system_time**
  OS system time
- **OS_idle_time**
  OS idle time
OS idle time
• exec_time
  Thread execution time
• sleep_time
  Thread sleep time
• spin_time
  Thread spin time
• send_time
  Thread send time
• buffer_full_time
  Thread buffer full time
• elapsed_time
  Elapsed time

25.6.17.22 The ndbinfo cpustat_20sec Table

The cpustat_20sec table provides raw, per-thread CPU data obtained each 20 seconds, for each thread running in the NDB kernel.

Like cpustat_50ms and cpustat_1sec, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, cpustat_20sec provides 400 seconds of history.

The cpustat_20sec table contains the following columns:
• node_id
  ID of the node where the thread is running
• thr_no
  Thread ID (specific to this node)
• OS_user_time
  OS user time
• OS_system_time
  OS system time
• OS_idle_time
  OS idle time
• exec_time
  Thread execution time
• sleep_time
  Thread sleep time
- spin_time
  Thread spin time
- send_time
  Thread send time
- buffer_full_time
  Thread buffer full time
- elapsed_time
  Elapsed time

25.6.17.23 The ndbinfo dictionary_columns Table

The table provides NDB dictionary information about columns of NDB tables. dictionary_columns has the columns listed here (with brief descriptions):

- table_id
  ID of the table containing the column
- column_id
  The column's unique ID
- name
  Name of the column
- column_type
  Data type of the column from the NDB API; see Column::Type, for possible values
- default_value
  The column's default value, if any
- nullable
  Either of NULL or NOT NULL
- array_type
  The column's internal attribute storage format; one of FIXED, SHORT_VAR, or MEDIUM_VAR; for more information, see Column::ArrayType, in the NDB API documentation
- storage_type
  Type of storage used by the table; either of MEMORY or DISK
- primary_key
  1 if this is a primary key column, otherwise 0
- partition_key
  1 if this is a partitioning key column, otherwise 0
- dynamic
1 if the column is dynamic, otherwise 0

• auto_inc
  1 if this is an AUTO_INCREMENT column, otherwise 0

You can obtain information about all of the columns in a given table by joining dictionary_columns with the dictionary_tables table, like this:

```sql
SELECT dc.*
FROM dictionary_columns dc
JOIN dictionary_tables dt
ON dc.table_id=dt.table_id
WHERE dt.table_name='t1'
AND dt.database_name='mydb';
```

Note
Blob columns are not shown in this table. This is a known issue.

25.6.17.24 The ndbinfo dictionary_tables Table

This table provides NDB dictionary information for NDB tables. dictionary_tables contains the columns listed here:

• table_id
  The table’s unique ID

• database_name
  Name of the database containing the table

• table_name
  Name of the table

• status
  The table status; one of New, Changed, Retrieved, Invalid, or Altered. (See Object::Status, for more information about object status values.)

• attributes
  Number of table attributes

• primary_key_cols
  Number of columns in the table’s primary key

• primary_key
  A comma-separated list of the columns in the table’s primary key

• storage
  Type of storage used by the table; one of memory, disk, or default

• logging
  Whether logging is enabled for this table

• dynamic
The NDB Cluster Information Database

1 if the table is dynamic, otherwise 0; the table is considered dynamic if `table->getForceVarPart()` is true, or if at least one table column is dynamic

- **read_backup**
  
  1 if read from any replica (READ_BACKUP option is enabled for this table, otherwise 0; see Section 15.1.20.12, “Setting NDB Comment Options”)

- **fully_replicated**
  
  1 if FULLY_REPLICATED is enabled for this table (each data node in the cluster has a complete copy of the table), 0 if not; see Section 15.1.20.12, “Setting NDB Comment Options”

- **checksum**
  
  If this table uses a checksum, the value in this column is 1; if not, it is 0

- **row_size**
  
  The amount of data, in bytes that can be stored in one row, not including any blob data stored separately in blob tables; see `Table::getRowSizeInBytes()`, in the API documentation, for more information

- **min_rows**
  
  Minimum number of rows, as used for calculating partitions; see `Table::getMinRows()`, in the API documentation, for more information

- **max_rows**
  
  Maximum number of rows, as used for calculating partitions; see `Table::getMaxRows()`, in the API documentation, for more information

- **tablespace**
  
  ID of the tablespace to which the table belongs, if any; this is 0, if the table does not use data on disk

- **fragment_type**
  
  The table’s fragment type; one of Single, AllSmall, AllMedium, AllLarge, DistrKeyHash, DistrKeyLin, UserDefined, unused, or HashMapPartition; for more information, see `Object::FragmentType`, in the NDB API documentation

- **hash_map**
  
  The hash map used by the table

- **fragments**
  
  Number of table fragments

- **partitions**
  
  Number of partitions used by the table

- **partition_balance**
  
  Type of partition balance used, if any; one of FOR_RP_BY_NODE, FOR_RA_BY_NODE, FOR_RP_BY_LDM, FOR_RA_BY_LDM, FOR_RA_BY_LDM_X_2, FOR_RA_BY_LDM_X_3, or FOR_RA_BY_LDM_X_4; see Section 15.1.20.12, “Setting NDB Comment Options”

- **contains_GCI**
