Yes. For tables created with the NDB storage engine, transactions are supported. Currently, NDB Cluster supports only the READ COMMITTED transaction isolation level.

### A.10.20 What storage engines are supported by NDB Cluster?

NDB Cluster requires the NDB storage engine. That is, in order for a table to be shared between nodes in an NDB Cluster, the table must be created using `ENGINE=NDB` (or the equivalent option `ENGINE=NDBCLUSTER`).
It is possible to create tables using other storage engines (such as InnoDB or MyISAM) on a MySQL server being used with NDB Cluster, but since these tables do not use NDB, they do not participate in clustering; each such table is strictly local to the individual MySQL server instance on which it is created.

NDB Cluster is quite different from InnoDB clustering with regard to architecture, requirements, and implementation; despite any similarity in their names, the two are not compatible. For more information about InnoDB clustering, see MySQL AdminAPI. See also Section 25.2.6, “MySQL Server Using InnoDB Compared with NDB Cluster”, for information about the differences between the NDB and InnoDB storage engines.

**A.10.21** In the event of a catastrophic failure— for example, the whole city loses power and my UPS fails—would I lose all my data?

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

**A.10.22** Is it possible to use FULLTEXT indexes with NDB Cluster?

FULLTEXT indexing is currently supported only by the InnoDB and MyISAM storage engines. See Section 14.9, “Full-Text Search Functions”, for more information.

**A.10.23** Can I run multiple nodes on a single computer?

It is possible but not always advisable. One of the chief reasons to run a cluster is to provide redundancy. To obtain the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. For this reason, if you do run multiple data nodes on a single machine, it is extremely important that they be set up in such a way that the failure of this machine does not cause the loss of all the data nodes in a given node group.

Given that NDB Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 300 MHz Pentium or equivalent CPU and sufficient RAM for the operating system, plus a small amount of overhead for the ndb_mgmd and ndb_mgm processes.

It is acceptable to run multiple cluster data nodes on a single host that has multiple CPUs, cores, or both. The NDB Cluster distribution also provides a multithreaded version of the data node binary intended for use on such systems. For more information, see Section 25.5.3, “ndb_mtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”. It is also possible in some cases to run data nodes and SQL nodes concurrently on the same machine; how well such an arrangement performs is dependent on a number of factors such as number of cores and CPUs as well as the amount of disk and memory available to the data node and SQL node processes, and you must take these factors into account when planning such a configuration.

**A.10.24** Can I add data nodes to an NDB Cluster without restarting it?

It is possible to add new data nodes to a running NDB Cluster without taking the cluster offline. For more information, see Section 25.6.7, “Adding NDB Cluster Data Nodes Online”.
For other types of NDB Cluster nodes, a rolling restart is all that is required (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”).

**A.10.25** Are there any limitations that I should be aware of when using NDB Cluster?

Limitations on NDB tables in MySQL NDB Cluster include the following:

- Temporary tables are not supported; a `CREATE TEMPORARY TABLE` statement using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` fails with an error.

- The only types of user-defined partitioning supported for `NDBCLUSTER` tables are `KEY` and `LINEAR KEY`. Trying to create an `NDB` table using any other partitioning type fails with an error.

- `FULLTEXT` indexes are not supported.

- Index prefixes are not supported. Only complete columns may be indexed.

- Spatial indexes are not supported (although spatial columns can be used). See Section 13.4, “Spatial Data Types”.

- Support for partial transactions and partial rollbacks is comparable to that of other transactional storage engines such as InnoDB that can roll back individual statements.

- The maximum number of attributes allowed per table is 512. Attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.

- Prior to NDB 8.0, the maximum size for a table row is 14 kilobytes, not counting BLOB values. In NDB 8.0, this maximum is increased to 30000 bytes. See Section 25.2.7.5, “Limits Associated with Database Objects in NDB Cluster”, for more information.

There is no set limit for the number of rows per NDB table. Limits on table size depend on a number of factors, in particular on the amount of RAM available to each data node.

For a complete listing of limitations in NDB Cluster, see Section 25.2.7, “Known Limitations of NDB Cluster”. See also Section 25.2.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.4”.

**A.10.26** Does NDB Cluster support foreign keys?

NDB Cluster provides support for foreign key constraints which is comparable to that found in the InnoDB storage engine; see Section 1.7.3.2, “FOREIGN KEY Constraints”, for more detailed information, as well as Section 15.1.20.5, “FOREIGN KEY Constraints”. Applications requiring foreign key support should use NDB Cluster 7.3, 7.4, 7.5, or later.

**A.10.27** How do I import an existing MySQL database into an NDB Cluster?

You can import databases into NDB Cluster much as you would with any other version of MySQL. Other than the limitations mentioned elsewhere in this FAQ, the only other special requirement is that any tables to be included in the cluster must use the NDB storage engine. This means that the tables must be created with `ENGINE=NDB` or `ENGINE=NDBCLUSTER`.

It is also possible to convert existing tables that use other storage engines to `NDBCLUSTER` using one or more `ALTER TABLE` statement. However, the definition of the table must be compatible with the `NDBCLUSTER` storage engine prior to making the conversion. In MySQL 8.4, an additional workaround is also required; see Section 25.2.7, “Known Limitations of NDB Cluster”, for details.

**A.10.28** How do NDB Cluster nodes communicate with one another?
Cluster nodes can communicate through any of three different transport mechanisms: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host; however, this is considered experimental. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See Section 25.4.4, “Using High-Speed Interconnects with NDB Cluster”, for more about using SCI as a transport mechanism for NDB Cluster.

**A.10.29** What is an arbitrator?

If one or more data nodes in a cluster fail, it is possible that not all cluster data nodes are able to “see” one another. In fact, it is possible that two sets of data nodes might become isolated from one another in a network partitioning, also known as a “split-brain” scenario. This type of situation is undesirable because each set of data nodes tries to behave as though it is the entire cluster. An arbitrator is required to decide between the competing sets of data nodes.

When all data nodes in at least one node group are alive, network partitioning is not an issue, because no single subset of the cluster can form a functional cluster on its own. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the “split-brain” scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognize the same node as the arbitrator, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbitrator selection is controlled by the `ArbitrationRank` configuration parameter for MySQL Server and management server nodes. You can also use the `ArbitrationRank` configuration parameter to control the arbitrator selection process. For more information about these parameters, see Section 25.4.3.5, “Defining an NDB Cluster Management Server”.

The role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

**A.10.30** What data types are supported by NDB Cluster?

NDB Cluster supports all of the usual MySQL data types, including those associated with MySQL’s spatial extensions; however, the NDB storage engine does not support spatial indexes. (Spatial indexes are supported only by MyISAM; see Section 13.4, “Spatial Data Types”, for more information.) In addition, there are some differences with regard to indexes when used with NDB tables.

**Note**

NDB Cluster Disk Data tables (that is, tables created with `TABLESPACE ... STORAGE DISK ENGINE=NDB` or `TABLESPACE ... STORAGE DISK ENGINE=NDBCLUSTER`) have only fixed-width rows. This means that (for example) each Disk Data table record containing a `VARCHAR(255)` column requires space for 255 characters (as required for the character set and collation being used for the table), regardless of the actual number of characters stored therein.

See Section 25.2.7, “Known Limitations of NDB Cluster”, for more information about these issues.

**A.10.31** How do I start and stop NDB Cluster?

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node, using the `ndb_mgmd` command.
When starting the cluster for the first time, you must include the `--config-file` option to tell the management node where its configuration file can be found.

2. Start each data node with the `ndbd` command.

   Each data node must be started with the `--ndb-connectstring` option so that the data node knows how to connect to the management server.

3. Start each MySQL Server (SQL node) using your preferred startup script, such as `mysql_safe`.

   Each MySQL Server must be started with the `--ndbcluster` and `--ndb-connectstring` options. These options cause `mysqld` to enable NDBCLUSTER storage engine support and how to connect to the management server.

Each of these commands must be run from a system shell on the machine housing the affected node. (You do not have to be physically present at the machine—a remote login shell can be used for this purpose.) You can verify that the cluster is running by starting the `ndb_mgm` on the machine housing the management node and issuing the `SHOW` or `ALL STATUS` command.

To shut down a running cluster, issue the command `SHUTDOWN` in the management client. Alternatively, you may enter the following command in a system shell:

```
$> ndb_mgm -e "SHUTDOWN"
```

(The quotation marks in this example are optional, since there are no spaces in the command string following the `-e` option; in addition, the `SHUTDOWN` command, like other management client commands, is not case-sensitive.)

Either of these commands causes the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as SQL nodes can be stopped using `mysqladmin shutdown`.

For more information, see Section 25.6.1, "Commands in the NDB Cluster Management Client", and Section 25.3.6, "Safe Shutdown and Restart of NDB Cluster".

MySQL Cluster Manager provides additional ways to handle starting and stopping of NDB Cluster nodes. See MySQL Cluster Manager 8.4.0 User Manual, for more information about this tool.

**A.10.32** What happens to NDB Cluster data when the cluster is shut down?

The data that was held in memory by the cluster’s data nodes is written to disk, and is reloaded into memory the next time that the cluster is started.

**A.10.33** Is it a good idea to have more than one management node for an NDB Cluster?

It can be helpful as a fail-safe. Only one management node controls the cluster at any given time, but it is possible to configure one management node as primary, and one or more additional management nodes to take over in the event that the primary management node fails.

See Section 25.4.3, “NDB Cluster Configuration Files”, for information on how to configure NDB Cluster management nodes.

**A.10.34** Can I mix different kinds of hardware and operating systems in one NDB Cluster?

Yes, as long as all machines and operating systems have the same "endianness" (all big-endian or all little-endian).
It is also possible to use software from different NDB Cluster releases on different nodes. However, we support such use only as part of a rolling upgrade procedure (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”).

**A.10.35.** Can I run two data nodes on a single host? Two SQL nodes?

Yes, it is possible to do this. In the case of multiple data nodes, it is advisable (but not required) for each node to use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of `mysqld` must use a different TCP/IP port.

Running data nodes and SQL nodes together on the same host is possible, but you should be aware that the `ndbd` or `ndbmtd` processes may compete for memory with `mysqld`.

**A.10.36.** Can I use host names with NDB Cluster?

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, you should use fixed (numeric) IP addresses, since making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional potential points of failure.

**A.10.37.** Does NDB Cluster support IPv6?

IPv6 is supported for connections between SQL nodes (MySQL servers), but connections between all other types of NDB Cluster nodes must use IPv4.

In practical terms, this means that you can use IPv6 for replication between NDB Clusters, but connections between nodes in the same NDB Cluster must use IPv4. For more information, see Section 25.7.3, “Known Issues in NDB Cluster Replication”.

**A.10.38.** How do I handle MySQL users in an NDB Cluster having multiple MySQL servers?

MySQL user accounts and privileges are normally not automatically propagated between different MySQL servers accessing the same NDB Cluster. MySQL NDB Cluster provides support for shared and synchronized users and privileges using the `NDB_STORED_USER` privilege; see Distributed Privileges Using Shared Grant Tables, for more information. You should be aware that this implementation was introduced in NDB 8.0, and is not compatible with the shared privileges mechanism employed in earlier versions of NDB Cluster. The older implementation is no longer supported in NDB 8.0.

**A.10.39.** How do I continue to send queries in the event that one of the SQL nodes fails?

MySQL NDB Cluster does not provide any sort of automatic failover between SQL nodes. Your application must be prepared to handle the loss of SQL nodes and to fail over between them.

**A.10.40.** How do I back up and restore an NDB Cluster?

You can use the NDB Cluster native backup and restore functionality in the NDB management client and the `ndb_restore` program. See Section 25.6.8, “Online Backup of NDB Cluster”, and Section 25.5.23, “ndb_restore — Restore an NDB Cluster Backup”.

You can also use the traditional functionality provided for this purpose in `mysqldump` and the MySQL server. See Section 6.5.4, “mysqldump — A Database Backup Program”, for more information.

**A.10.41.** What is an “angel process”?

This process monitors and, if necessary, attempts to restart the data node process. If you check the list of active processes on your system after starting `ndbd`, you can see that there are actually 2
A.11 MySQL 8.4 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

This set of Frequently Asked Questions derives from the experience of MySQL's Support and Development groups in handling many inquiries about CJK (Chinese-Japanese-Korean) issues.

A.11.1 What CJK character sets are available in MySQL? ................................................................. 5396
A.11.2 I have inserted CJK characters into my table. Why does SELECT display them as “?” characters? ........................................................................................................................................ 5398
A.11.3 What problems should I be aware of when working with the Big5 Chinese character set? ...... 5400
A.11.4 Why do Japanese character set conversions fail? ................................................................. 5400
A.11.5 What should I do if I want to convert SJIS 81CA to CP932? ............................................. 5401
A.11.6 How does MySQL represent the Yen (¥) sign? ..................................................................... 5401
A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL? ...... 5401
A.11.8 Why do I get Incorrect string value error messages? ......................................................... 5402
A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API? ................................................................. 5402
A.11.10 I've upgraded to MySQL 8.4. How can I revert to behavior like that in MySQL 4.0 with regard to character sets? ....................................................................................................................... 5403
A.11.11 Why do some LIKE and FULLTEXT searches with CJK characters fail? .......................... 5404
A.11.12 How do I know whether character X is available in all character sets? ............................. 5405
A.11.13 Why do CJK strings sort incorrectly in Unicode? (I) ......................................................... 5406
A.11.14 Why do CJK strings sort incorrectly in Unicode? (II) ....................................................... 5406
A.11.15 Why are my supplementary characters rejected by MySQL? ............................................. 5406
A.11.16 Should “CJK” be “CJKV”? ..................................................................................................... 5407
A.11.17 Does MySQL permit CJK characters to be used in database and table names? ................. 5407
A.11.18 Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean? ... 5407
A.11.19 Where can I get help with CJK and related issues in MySQL? ........................................... 5407

A.11.1 What CJK character sets are available in MySQL?

The list of CJK character sets may vary depending on your MySQL version. For example, the gb18030 character set is not supported prior to MySQL 5.7.4. However, since the name of the applicable language appears in the DESCRIPTION column for every entry in the
INFORMATION_SCHEMA.CHARACTER_SETS table, you can obtain a current list of all the non-Unicode CJK character sets using this query:

```
mysql> SELECT CHARACTER_SET_NAME, DESCRIPTION
FROM INFORMATION_SCHEMA.CHARACTER_SETS
WHERE DESCRIPTION LIKE '%Chin%'
OR DESCRIPTION LIKE '%Japanese%'
OR DESCRIPTION LIKE '%Korean%'
ORDER BY CHARACTER_SET_NAME;
```

<table>
<thead>
<tr>
<th>CHARACTER_SET_NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>big5</td>
<td>Big5 Traditional Chinese</td>
</tr>
<tr>
<td>cp932</td>
<td>SJIS for Windows Japanese</td>
</tr>
<tr>
<td>eucjpms</td>
<td>UJIS for Windows Japanese</td>
</tr>
<tr>
<td>euckr</td>
<td>EUC-KR Korean</td>
</tr>
<tr>
<td>gb18030</td>
<td>China National Standard GB18030</td>
</tr>
<tr>
<td>gb2312</td>
<td>GB2312 Simplified Chinese</td>
</tr>
<tr>
<td>gbk</td>
<td>GBK Simplified Chinese</td>
</tr>
<tr>
<td>sjis</td>
<td>Shift-JIS Japanese</td>
</tr>
<tr>
<td>ujis</td>
<td>EUC-JP Japanese</td>
</tr>
</tbody>
</table>

(For more information, see Section 28.3.4, "The INFORMATION_SCHEMA CHARACTER_SETS Table").

MySQL supports three variants of the GB (Guojia Biaozhun, or National Standard, or Simplified Chinese) character sets which are official in the People's Republic of China: gb2312, gbk, and (as of MySQL 5.7.4) gb18030.

Sometimes people try to insert gbk characters into gb2312, and it works most of the time because gbk is a superset of gb2312. But eventually they try to insert a rarer Chinese character and it does not work. (For an example, see Bug #16072).

Here, we try to clarify exactly what characters are legitimate in gb2312 or gbk, with reference to the official documents. Please check these references before reporting gb2312 or gbk bugs:

- The MySQL gbk character set is in reality “Microsoft code page 936”. This differs from the official gbk for characters A1A4 (middle dot), A1AA (em dash), A6E0–A6F5, and A8BB–A8C0.
- For a listing of gbk/Unicode mappings, see http://www.unicode.org/Public/MAPPINGS/VENDORS/MICSFT/WINDOWS/CP936.TXT.

It is also possible to store CJK characters in Unicode character sets, although the available collations may not sort characters quite as you expect:

- The utf8 and ucs2 character sets support the characters from Unicode Basic Multilingual Plane (BMP). These characters have code point values between \u0000 and \uFFFF.
- The utf8mb4, utf16, utf16le, and utf32 character sets support BMP characters, as well as supplementary characters that lie outside the BMP. Supplementary characters have code point values between \u10000 and \u10FFFF.

The collation used for a Unicode character set determines the ability to sort (that is, distinguish) characters in the set:

- Collations based on Unicode Collation Algorithm (UCA) 4.0.0 distinguish only BMP characters.
- Collations based on UCA 5.2.0 or 9.0.0 distinguish BMP and supplementary characters.
Non-UCA collations may not distinguish all Unicode characters. For example, the utf8mb4 default collation is utf8mb4_general_ci, which distinguishes only BMP characters.

Moreover, distinguishing characters is not the same as ordering them per the conventions of a given CJK language. Currently, MySQL has only one CJK-specific UCA collation, gb18030_unicode_520_ci (which requires use of the non-Unicode gb18030 character set).

For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see Section 12.10.1, “Unicode Character Sets”.

**A.11.2** I have inserted CJK characters into my table. Why does `SELECT` display them as “?” characters?

This problem is usually due to a setting in MySQL that does not match the settings for the application program or the operating system. Here are some common steps for correcting these types of issues:

- **Be certain of what MySQL version you are using.**

  Use the statement `SELECT VERSION();` to determine this.

- **Make sure that the database is actually using the desired character set.**

  People often think that the client character set is always the same as either the server character set or the character set used for display purposes. However, both of these are false assumptions. You can make sure by checking the result of `SHOW CREATE TABLE tablename` or, better yet, by using this statement:

  ```sql
  SELECT character_set_name, collation_name
  FROM information_schema.columns
  WHERE table_schema = your_database_name
  AND table_name = your_table_name
  AND column_name = your_column_name;
  ```

- **Determine the hexadecimal value of the character or characters that are not being displayed correctly.**

  You can obtain this information for a column `column_name` in the table `table_name` using the following query:

  ```sql
  SELECT HEX(column_name)
  FROM table_name;
  ```

  `3F` is the encoding for the “?” character; this means that “?” is the character actually stored in the column. This most often happens because of a problem converting a particular character from your client character set to the target character set.
• **Make sure that a round trip is possible. When you select literal (or _introducer hexadecimal-value), do you obtain literal as a result?**

For example, the Japanese Katakana character `ペ` (ペ) exists in all CJK character sets, and has the code point value (hexadecimal coding) \(0x30da\). To test a round trip for this character, use this query:

```sql
SELECT 'ペ' AS `ペ`;         /* or SELECT _ucs2 0x30da; */
```

If the result is not also `ペ`, the round trip failed.

For bug reports regarding such failures, we might ask you to follow up with `SELECT HEX('ペ');`. Then we can determine whether the client encoding is correct.

• **Make sure that the problem is not with the browser or other application, rather than with MySQL.**

Use the `mysql` client program to accomplish this task. If `mysql` displays characters correctly but your application does not, your problem is probably due to system settings.

To determine your settings, use the `SHOW VARIABLES` statement, whose output should resemble what is shown here:

```sql
mysql> SHOW VARIABLES LIKE 'char%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>character_set_client</td>
<td>utf8</td>
<td>utf8</td>
</tr>
<tr>
<td>character_set_connection</td>
<td>utf8</td>
<td>utf8</td>
</tr>
<tr>
<td>character_set_database</td>
<td>latin1</td>
<td>latin1</td>
</tr>
<tr>
<td>character_set_filesystem</td>
<td>binary</td>
<td>binary</td>
</tr>
<tr>
<td>character_set_results</td>
<td>utf8</td>
<td>utf8</td>
</tr>
<tr>
<td>character_set_server</td>
<td>latin1</td>
<td>latin1</td>
</tr>
<tr>
<td>character_set_system</td>
<td>utf8</td>
<td>utf8</td>
</tr>
<tr>
<td>character_sets_dir</td>
<td>/usr/local/mysql/share/mysql/charsets/</td>
<td>/usr/local/mysql/share/mysql/charsets/</td>
</tr>
</tbody>
</table>

These are typical character-set settings for an international-oriented client (notice the use of `utf8` Unicode) connected to a server in the West (`latin1` is a West Europe character set).

Although Unicode (usually the `utf8` variant on Unix, and the `ucs2` variant on Windows) is preferable to Latin, it is often not what your operating system utilities support best. Many Windows users find that a Microsoft character set, such as `cp932` for Japanese Windows, is suitable.

If you cannot control the server settings, and you have no idea what setting your underlying computer uses, try changing to a common character set for the country that you’re in (`euckr` = Korea; `gb18030`, `gb2312` or `gbk` = People's Republic of China; `big5` = Taiwan; `sjis`, `ujis`, `cp932`, or `eucjpms` = Japan; `ucs2` or `utf8` = anywhere). Usually it is necessary to change only the client and connection and results settings. The `SET NAMES` statement changes all three at once. For example:

```sql
SET NAMES 'big5';
```

Once the setting is correct, you can make it permanent by editing `my.cnf` or `my.ini`. For example you might add lines looking like these:

```ini
[mysqld]
character-set-server=big5
```

```ini
[client]
```
default-character-set=big5

It is also possible that there are issues with the API configuration setting being used in your application; see Why does my GUI front end or browser not display CJK characters correctly...? for more information.

A.11.3 What problems should I be aware of when working with the Big5 Chinese character set?

MySQL supports the Big5 character set which is common in Hong Kong and Taiwan (Republic of China). The MySQL big5 character set is in reality Microsoft code page 950, which is very similar to the original big5 character set.

A feature request for adding HKSCS extensions has been filed. People who need this extension may find the suggested patch for Bug #13577 to be of interest.

A.11.4 Why do Japanese character set conversions fail?

MySQL supports the sjis, ujis, cp932, and eucjpms character sets, as well as Unicode. A common need is to convert between character sets. For example, there might be a Unix server (typically with sjis or ujis) and a Windows client (typically with cp932).

In the following conversion table, the ucs2 column represents the source, and the sjis, cp932, ujis, and eucjpms columns represent the destinations; that is, the last 4 columns provide the hexadecimal result when we use CONVERT(ucs2) or we assign a ucs2 column containing the value to an sjis, cp932, ujis, or eucjpms column.

<td>3F</td>
<td>A2CC</td>
</tr>
</tbody>
</table>

This means that MySQL converts the NOT SIGN (Unicode U+00AC) to sjis code point 0x81CA and to cp932 code point 3F. (3F is the question mark ("?"). This is what is always used when the conversion cannot be performed.)

A.11.5 What should I do if I want to convert SJIS 81CA to cp932?

Our answer is: “?” . There are disadvantages to this, and many people would prefer a “loose” conversion, so that 81CA (NOT SIGN) in sjis becomes 81CA (FULLWIDTH NOT SIGN) in cp932.

A.11.6 How does MySQL represent the Yen (¥) sign?

A problem arises because some versions of Japanese character sets (both sjis and euc) treat 5C as a reverse solidus (\, also known as a backslash), whereas others treat it as a yen sign (¥).

MySQL follows only one version of the JIS (Japanese Industrial Standards) standard description. In MySQL, 5C is always the reverse solidus (\).

A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL?

In theory, while there have been several versions of the euckr (Extended Unix Code Korea) character set, only one problem has been noted. We use the “ASCII” variant of EUC-KR, in which the code point 0x5c is REVERSE SOLIDUS, that is \, instead of the “KS-Roman” variant of EUC-KR, in which the code point 0x5c is WON SIGN (₩). This means that you cannot convert Unicode U+20A9 to euckr:

```
mysql> SELECT CONVERT('₩' USING euckr) AS euckr;
```
A.11.8 Why do I get *Incorrect string value* error messages?

To see the problem, create a table with one Unicode (ucs2) column and one Chinese (gb2312) column.

```
mysql> CREATE TABLE ch
(ucs2 CHAR(3) CHARACTER SET ucs2,
 gb2312 CHAR(3) CHARACTER SET gb2312);
```

In nonstrict SQL mode, try to place the rare character 汽 in both columns.

```
mysql> SET sql_mode = '';
mysql> INSERT INTO ch VALUES ('A汽B','A汽B');
Query OK, 1 row affected, 1 warning (0.00 sec)
```

The *INSERT* produces a warning. Use the following statement to see what it is:

```
mysql> SHOW WARNINGS\G
```

```
*************************** 1. row ***************************
Level: Warning
Code: 1366
Message: Incorrect string value: '\xE6\xB1\x8CB' for column 'gb2312' at row 1
```

So it is a warning about the *gb2312* column only.

```
mysql> SELECT ucs2,HEX(ucs2),gb2312,HEX(gb2312) FROM ch;
```

```
+-------+--------------+--------+-------------+
<table>
<thead>
<tr>
<th>ucs2</th>
<th>HEX(ucs2)</th>
<th>gb2312</th>
<th>HEX(gb2312)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A汽B</td>
<td>00416C4C0042</td>
<td>A?B</td>
<td>413F42</td>
</tr>
</tbody>
</table>
+-------+--------------+--------+-------------+
```

Several things need explanation here:

1. The 汽 character is not in the *gb2312* character set, as described earlier.
2. If you are using an old version of MySQL, you may see a different message.
3. A warning occurs rather than an error because MySQL is not set to use strict SQL mode. In nonstrict mode, MySQL tries to do what it can, to get the best fit, rather than give up. With strict SQL mode, the *Incorrect string value* message occurs as an error rather than a warning, and the *INSERT* fails.

A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API?

Obtain a direct connection to the server using the *mysql* client, and try the same query there. If *mysql* responds correctly, the trouble may be that your application interface requires initialization. Use *mysql* to tell you what character set or sets it uses with the statement *

```
SHOW VARIABLES LIKE 'char%';
```

If you are using Access, you are most likely connecting with Connector/ODBC. In this case, you should check Configuring Connector/ODBC. If, for example, you use *big5*, you would enter *SET NAMES 'big5'*. (In this case, no ; character is required.) If you are using ASP, you might need to add *SET NAMES* in the code. Here is an example that has worked in the past:
In much the same way, if you are using any character set other than latin1 with Connector/NET, you must specify the character set in the connection string. See Connector/NET Connections, for more information.

If you are using PHP, try this:

```php
<?php
$link = new mysqli($host, $usr, $pwd, $db);
if( mysqli_connect_errno() )
{
 printf("Connect failed: %s\n", mysqli_connect_error());
 exit();
}
$link->query("SET NAMES 'utf8'");
?>
```

In this case, we used SET NAMES to change character_set_client, 
character_set_connection, and character_set_results.

Another issue often encountered in PHP applications has to do with assumptions made by the browser. Sometimes adding or changing a <meta> tag suffices to correct the problem: for example, to insure that the user agent interprets page content as UTF-8, include <meta http-equiv="Content-Type" content="text/html; charset=utf-8"> in the <head> section of the HTML page.

If you are using Connector/J, see Using Character Sets and Unicode.

A.11.10 I've upgraded to MySQL 8.4. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?

In MySQL Version 4.0, there was a single “global” character set for both server and client, and the decision as to which character to use was made by the server administrator. This changed starting with MySQL Version 4.1. What happens now is a "handshake", as described in Section 12.4, “Connection Character Sets and Collations":

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the character_set_client, 
character_set_results, and character_set_connection system variables. In effect, the server performs a SET NAMES operation using the character set name.

The effect of this is that you cannot control the client character set by starting mysqld with --character-set-server=utf8. However, some Asian customers prefer the MySQL 4.0 behavior. To make it possible to retain this behavior, we added a mysqld switch, --character-set-client-handshake, which can be turned off with --skip-character-set-client-handshake. If you start mysqld with --skip-character-set-client-handshake, then,
when a client connects, it sends to the server the name of the character set that it wants to use. However, the server ignores this request from the client.

By way of example, suppose that your favorite server character set is latin1. Suppose further that the client uses utf8 because this is what the client's operating system supports. Start the server with latin1 as its default character set:

```bash
mysqld --character-set-server=latin1
```

And then start the client with the default character set utf8:

```bash
mysql --default-character-set=utf8
```

The resulting settings can be seen by viewing the output of `SHOW VARIABLES`:

```sql
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
```

Now stop the client, and stop the server using `mysqladmin`. Then start the server again, but this time tell it to skip the handshake like so:

```bash
mysqld --character-set-server=utf8 --skip-character-set-client-handshake
```

Start the client with utf8 once again as the default character set, then display the resulting settings:

```sql
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | latin1                                 |
| character_set_connection | latin1                                 |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | latin1                                 |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
```

As you can see by comparing the differing results from `SHOW VARIABLES`, the server ignores the client's initial settings if the `--skip-character-set-client-handshake` option is used.

**A.11.1 Why do some LIKE and FULLTEXT searches with CJK characters fail?**

For LIKE searches, there is a very simple problem with binary string column types such as BINARY and BLOB: we must know where characters end. With multibyte character sets, different characters might have different octet lengths. For example, in utf8, A requires one byte but 未 requires three bytes, as shown here:

```sql
| OCTET_LENGTH(_utf8 'A') | OCTET_LENGTH(_utf8 '未') |
+-------------------------+-------------------------|
| 5404                    | 3204                    |
```
If we do not know where the first character in a string ends, we do not know where the second character begins, in which case even very simple searches such as `LIKE '_A%'` fail. The solution is to use a nonbinary string column type defined to have the proper CJK character set. For example: `mycol TEXT CHARACTER SET sjis`. Alternatively, convert to a CJK character set before comparing.

This is one reason why MySQL cannot permit encodings of nonexistent characters. If it is not strict about rejecting bad input, it has no way of knowing where characters end.

For `FULLTEXT` searches, we must know where words begin and end. With Western languages, this is rarely a problem because most (if not all) of these use an easy-to-identify word boundary: the space character. However, this is not usually the case with Asian writing. We could use arbitrary halfway measures, like assuming that all Han characters represent words, or (for Japanese) depending on changes from Katakana to Hiragana due to grammatical endings. However, the only sure solution requires a comprehensive word list, which means that we would have to include a dictionary in the server for each Asian language supported. This is simply not feasible.

**A.11.12** How do I know whether character x is available in all character sets?

The majority of simplified Chinese and basic nonhalfwidth Japanese Kana characters appear in all CJK character sets. The following stored procedure accepts a `UCS-2` Unicode character, converts it to other character sets, and displays the results in hexadecimal.

```
DELIMITER //

CREATE PROCEDURE p_convert(ucs2_char CHAR(1) CHARACTER SET ucs2)
BEGIN

CREATE TABLE tj
( ucs2 CHAR(1) character set ucs2,
  utf8 CHAR(1) character set utf8,
  big5 CHAR(1) character set big5,
  cp932 CHAR(1) character set cp932,
  eucjpms CHAR(1) character set eucjpms,
  euckr CHAR(1) character set euckr,
  gb2312 CHAR(1) character set gb2312,
  gbk CHAR(1) character set gbk,
  sjis CHAR(1) character set sjis,
  ujis CHAR(1) character set ujis);

INSERT INTO tj (ucs2) VALUES (ucs2_char);

UPDATE tj SET utf8=ucs2,
          big5=ucs2,
          cp932=ucs2,
          eucjpms=ucs2,
          euckr=ucs2,
          gb2312=ucs2,
          gbk=ucs2,
          sjis=ucs2,
          ujis=ucs2;

/* If there are conversion problems, UPDATE produces warnings. */

SELECT hex(ucs2) AS ucs2,
       hex(utf8) AS utf8,
       hex(big5) AS big5,
       hex(cp932) AS cp932,
       hex(eucjpms) AS eucjpms,
       hex(euckr) AS euckr,
```
The input can be any single ucs2 character, or it can be the code value (hexadecimal representation) of that character. For example, from Unicode's list of ucs2 encodings and names (http://www.unicode.org/Public/UNIDATA/UnicodeData.txt), we know that the Katakana character Pe appears in all CJK character sets, and that its code value is X'30DA'. If we use this value as the argument to p_convert(), the result is as shown here:

```
mysql> CALL p_convert(X'30DA');
+--------+-----+--------+----------+--------+--------+--------+
| ucs2   | utf8 | big5   | cp932    | eucjpms | euckr  | gb2312  |
|--------+-----+--------+----------+--------+--------+--------+
| 30DA   | E3839A| C772   | 8379     | A5DA   | ABDA   | A5DA   |
+--------+-----+--------+----------+--------+--------+--------+
```

Since none of the column values is 3F (that is, the question mark character, ?), we know that every conversion worked.

A.11.13 Why do CJK strings sort incorrectly in Unicode? (I)

CJK sorting problems that occurred in older MySQL versions can be solved as of MySQL 8.0 by using the utf8mb4 character set and the utf8mb4_ja_0900_as_cs collation.

A.11.14 Why do CJK strings sort incorrectly in Unicode? (II)

CJK sorting problems that occurred in older MySQL versions can be solved as of MySQL 8.0 by using the utf8mb4 character set and the utf8mb4_ja_0900_as_cs collation.

A.11.15 Why are my supplementary characters rejected by MySQL?

Supplementary characters lie outside the Unicode Basic Multilingual Plane / Plane 0. BMP characters have code point values between U+0000 and U+FFFF. Supplementary characters have code point values between U+10000 and U+10FFFF.

To store supplementary characters, you must use a character set that permits them:

- The utf8 and ucs2 character sets support BMP characters only.

  The utf8 character set permits only UTF-8 characters that take up to three bytes. This has led to reports such as that found in Bug #12600, which we rejected as "not a bug". With utf8, MySQL must truncate an input string when it encounters bytes that it does not understand. Otherwise, it is unknown how long the bad multibyte character is.

  One possible workaround is to use ucs2 instead of utf8, in which case the "bad" characters are changed to question marks. However, no truncation takes place. You can also change the data type to BLOB or BINARY, which perform no validity checking.

- The utf8mb4, utf16, utf16le, and utf32 character sets support BMP characters, as well as supplementary characters outside the BMP.
A.11.16 Should “CJK” be “CJKV”?

No. The term “CJKV” (Chinese Japanese Korean Vietnamese) refers to Vietnamese character sets which contain Han (originally Chinese) characters. MySQL supports the modern Vietnamese script with Western characters, but does not support the old Vietnamese script using Han characters.

As of MySQL 5.6, there are Vietnamese collations for Unicode character sets, as described in Section 12.10.1, “Unicode Character Sets”.

A.11.17 Does MySQL permit CJK characters to be used in database and table names?

Yes.

A.11.18 Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean?

The Japanese translation of the MySQL 5.6 manual can be downloaded from https://dev.mysql.com/doc/.

A.11.19 Where can I get help with CJK and related issues in MySQL?

The following resources are available:

- A listing of MySQL user groups can be found at https://wikis.oracle.com/display/mysql/List+of+MySQL+User+Groups.
- View feature requests relating to character set issues at http://tinyurl.com/y6xcuf.

A.12 MySQL 8.4 FAQ: Connectors & APIs

For common questions, issues, and answers relating to the MySQL Connectors and other APIs, see the following areas of the Manual:

- Using C API Features
- Connector/ODBC Notes and Tips
- Connector/NET Programming
- MySQL Connector/J Developer Guide

A.13 MySQL 8.4 FAQ: C API, libmysql

Frequently asked questions about MySQL C API and libmysql.

A.13.1 What is “MySQL Native C API”? What are typical benefits and use cases? .......................... 5407
A.13.2 Which version of libmysql should I use? .............................................................................. 5408
A.13.3 What if I want to use the “NoSQL” X DevAPI? ................................................................. 5408
A.13.4 How to I download libmysql? .............................................................................................. 5408
A.13.5 Where is the documentation? .............................................................................................. 5408
A.13.6 How do I report bugs? ......................................................................................................... 5408
A.13.7 Is it possible to compile the library myself? ........................................................................ 5408

A.13.1 What is “MySQL Native C API”? What are typical benefits and use cases?
libmysql is a C-based API that you can use in C applications to connect with the MySQL database server. It is also itself used as the foundation for drivers for standard database APIs like ODBC, Perl's DBI, and Python's DB API.

A.13.2 Which version of libmysql should I use?

For MySQL 8.0, 5.7, 5.6, and 5.5, we recommend libmysql 8.0.

A.13.3 What if I want to use the "NoSQL" X DevAPI?

For C-language and X DevApi Document Store for MySQL 8.0, we recommend MySQL Connector/C++. Connector/C++ 8.0 has compatible C headers. (This is not applicable to MySQL 5.7 or before.)

A.13.4 How to I download libmysql?

- Linux: The Client Utilities Package is available from the MySQL Community Server download page.
- Repos: The Client Utilities Package is available from the Yum, APT, SuSE repositories.
- Windows: The Client Utilities Package is available from Windows Installer.

A.13.5 Where is the documentation?

See MySQL 8.4 C API Developer Guide.

A.13.6 How do I report bugs?

Please report any bugs or inconsistencies you observe to our Bugs Database. Select the C API Client as shown.

A.13.7 Is it possible to compile the library myself?

Compiling MySQL Server also compiles libmysqlclient; there is not a way to only compile libmysqlclient. For related information, see MySQL C API Implementations.

A.14 MySQL 8.4 FAQ: Replication

In the following section, we provide answers to questions that are most frequently asked about MySQL Replication.

A.14.1 Must the replica be connected to the source all the time? ........................................ 5409
A.14.2 Must I enable networking on my source and replica to enable replication? ....................... 5409
A.14.3 How do I know how late a replica is compared to the source? In other words, how do I know the date of the last statement replicated by the replica? .................................................. 5409
A.14.4 How do I force the source to block updates until the replica catches up? ............................. 5409
A.14.5 What issues should I be aware of when setting up two-way replication? ................................. 5410
A.14.6 How can I use replication to improve performance of my system? ...................................... 5410
A.14.7 What should I do to prepare client code in my own applications to use performance-enhancing replication? ........................................................................................................... 5410
A.14.8 When and how much can MySQL replication improve the performance of my system? ........ 5410
A.14.9 How can I use replication to provide redundancy or high availability? ................................. 5411
A.14.10 How do I tell whether a replication source server is using statement-based or row-based binary logging format? ................................................................................................. 5412
A.14.11 How do I tell a replica to use row-based replication? .......................................................... 5412
A.14.12 How do I prevent GRANT and REVOKE statements from replicating to replica machines? .... 5412
A.14.13 Does replication work on mixed operating systems (for example, the source runs on Linux while replicas run on macOS and Windows)?

No, it does not. The replica can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a source/replica relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the replica is not guaranteed to be in synchrony with the source unless you take some special measures.

To ensure that catchup can occur for a replica that has been disconnected, you must not remove binary log files from the source that contain information that has not yet been replicated to the replicas. Asynchronous replication can work only if the replica is able to continue reading the binary log from the point where it last read events.

A.14.14 Does replication work on mixed hardware architectures (for example, the source runs on a 64-bit machine while replicas run on 32-bit machines)?

Yes, networking must be enabled on the source and replica. If networking is not enabled, the replica cannot connect to the source and transfer the binary log. Verify that the `skip_networking` system variable has not been enabled in the configuration file for either server.

A.14.15 Must the replica be connected to the source all the time?

No, it does not. The replica can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a source/replica relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the replica is not guaranteed to be in synchrony with the source unless you take some special measures.

To ensure that catchup can occur for a replica that has been disconnected, you must not remove binary log files from the source that contain information that has not yet been replicated to the replicas. Asynchronous replication can work only if the replica is able to continue reading the binary log from the point where it last read events.

A.14.2 Must I enable networking on my source and replica to enable replication?

Yes, networking must be enabled on the source and replica. If networking is not enabled, the replica cannot connect to the source and transfer the binary log. Verify that the `skip_networking` system variable has not been enabled in the configuration file for either server.

A.14.3 How do I know how late a replica is compared to the source? In other words, how do I know the date of the last statement replicated by the replica?

Check the `Seconds_Behind_Master` column in the output from `SHOW REPLICA | SLAVE STATUS`. See Section 19.1.7.1, "Checking Replication Status".

When the replication SQL thread executes an event read from the source, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the replication SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the replica machine. You can use this to determine the date of the last replicated event. Note that if your replica has been disconnected from the source for one hour, and then reconnects, you may immediately see large Time values such as 3600 for the replication SQL thread in `SHOW PROCESSLIST`. This is because the replica is executing statements that are one hour old. See Section 19.2.3, "Replication Threads".

A.14.4 How do I force the source to block updates until the replica catches up?

Use the following procedure:

1. On the source, execute these statements:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SHOW MASTER STATUS;
   ```

   Record the replication coordinates (the current binary log file name and position) from the output of the `SHOW` statement.

2. On the replica, issue the following statement, where the arguments to the `SOURCE_POS_WAIT()` or `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

   ```
   mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
   ```
The `SELECT` statement blocks until the replica reaches the specified log file and position. At that point, the replica is in synchrony with the source and the statement returns.

3. On the source, issue the following statement to enable the source to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

**A.14.5** What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between source and replica to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-source 1, and in the meantime, before it propagates to co-source 2, client B could make an update to co-source 2 that makes the update of client A work differently than it did on co-source 1. Thus, when the update of client A makes it to co-source 2, it produces tables that are different from what you have on co-source 1, even after all the updates from co-source 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one replication thread. Even this benefit might be offset by network delays.

**A.14.6** How can I use replication to improve performance of my system?

Set up one server as the source and direct all writes to it. Then configure as many replicas as you have the budget and rackspace for, and distribute the reads among the source and the replicas. You can also start the replicas with the `--skip-innodb` option, enable the `low_priority_updates` system variable, and set the `delay_key_write` system variable to `ALL` to get speed improvements on the replica end. In this case, the replica uses nontransactional MyISAM tables instead of InnoDB tables to get more speed by eliminating transactional overhead.

**A.14.7** What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, Section 19.4.5, “Using Replication for Scale-Out”.

**A.14.8** When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-source/multiple-replica setup, you can scale the system by adding more replicas until you either run out of network bandwidth, or your update load grows to the point that the source cannot handle it.

To determine how many replicas you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical source and a typical replica. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let `reads` and `writes` denote the number of reads and writes per second, respectively.
Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that reads is 1200 - 2 * writes. In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the source and each replica have the same capacity, and that we have one source and \( N \) replicas. Then we have for each server (source or replica):

\[
\text{reads} = 1200 - 2 \times \text{writes}
\]

\[
\text{reads} = \frac{9 \times \text{writes}}{N + 1} \quad \text{(reads are split, but writes replicated to all replicas)}
\]

\[
9 \times \text{writes} / (N + 1) + 2 \times \text{writes} = 1200
\]

\[
\text{writes} = \frac{1200}{2 + 9/(N + 1)}
\]

The last equation indicates the maximum number of writes for \( N \) replicas, given a maximum possible read rate of 1,200 per second and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If \( N = 0 \) (which means we have no replication), our system can handle about \( 1200/11 = 109 \) writes per second.
- If \( N = 1 \), we get up to 184 writes per second.
- If \( N = 8 \), we get up to 400 writes per second.
- If \( N = 17 \), we get up to 480 writes per second.
- Eventually, as \( N \) approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

These computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what happens on your system if you add \( N \) replicas. However, answering the following questions should help you decide whether and by how much replication may improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many replicas do you have bandwidth available on your network?

**A.14.9** How can I use replication to provide redundancy or high availability?

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the replica.

To handle the process manually, you should be able to switch from a failed source to a pre-configured replica by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see Section 19.4.8, “Switching Sources During Failover”.

5411
A.14.10 How do I tell whether a replication source server is using statement-based or row-based binary logging format?

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown is always one of STATEMENT, ROW, or MIXED. For MIXED mode, statement-based logging is used by default but replication switches automatically to row-based logging under certain conditions, such as unsafe statements. For information about when this may occur, see Section 7.4.4.3, “Mixed Binary Logging Format”.

A.14.11 How do I tell a replica to use row-based replication?

Replicas automatically know which format to use.

A.14.12 How do I prevent `GRANT` and `REVOKE` statements from replicating to replica machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option to ignore replication for tables in the `mysql` database.

A.14.13 Does replication work on mixed operating systems (for example, the source runs on Linux while replicas run on macOS and Windows)?

Yes.

A.14.14 Does replication work on mixed hardware architectures (for example, the source runs on a 64-bit machine while replicas run on 32-bit machines)?

Yes.

A.15 MySQL 8.4 FAQ: MySQL Enterprise Thread Pool

A.15.1 What is the Thread Pool and what problem does it solve?

The MySQL Thread Pool is a MySQL server plugin that extends the default connection-handling capabilities of the MySQL server to limit the number of concurrently executing statements/queries and transactions to ensure that each has sufficient CPU and memory resources to fulfill its task. For MySQL 8.4, the Thread Pool plugin is included in MySQL Enterprise Edition, a commercial product.

The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The Thread Pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The Thread Pool plugin increases server performance by efficiently managing statement execution threads for large numbers of client connections, especially on modern multi-CPU/Core systems.

For more information, see Section 7.6.3, “MySQL Enterprise Thread Pool”.

A.15.2 How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput?
The Thread Pool uses a “divide and conquer” approach to limiting and balancing concurrency. Unlike the default connection handling of the MySQL Server, the Thread Pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. The Thread Pool then manages client connections within configurable thread groups, where they are prioritized and queued based on the nature of the work they were submitted to accomplish.

For more information, see Section 7.6.3.3, “Thread Pool Operation”.

A.15.3 How is the Thread Pool different from the client side Connection Pool?

The MySQL Connection Pool operates on the client side to ensure that a MySQL client does not constantly connect to and disconnect from the MySQL server. It is designed to cache idle connections in the MySQL client for use by other users as they are needed. This minimizes the overhead and expense of establishing and tearing down connections as queries are submitted to the MySQL server. The MySQL Connection Pool has no visibility as to the query handling capabilities or load of the back-end MySQL server. By contrast, the Thread Pool operates on the MySQL server side and is designed to manage the execution of inbound concurrent connections and queries as they are received from the client connections accessing the back-end MySQL database. Because of the separation of duties, the MySQL Connection Pool and Thread Pool are orthogonal and can be used independent of each other.

MySQL Connection Pooling via the MySQL Connectors is covered in Chapter 31, Connectors and APIs.

A.15.4 When should I use the Thread Pool?

There are a few rules of thumb to consider for optimal Thread Pool use cases:

The MySQL Threads_running variable keeps track of the number of concurrent statements currently executing in the MySQL Server. If this variable consistently exceeds a region where the server won't operate optimally (usually going beyond 40 for InnoDB workloads), the Thread Pool should be beneficial, especially in extreme parallel overload situations.

If you are using the innodb_thread_concurrency to limit the number of concurrently executing statements, you should find that the Thread Pool solves the same problem, only better, by assigning connections to thread groups, then queuing executions based on transactional content, user defined designations, and so forth.

Lastly, if your workload comprises mainly short queries, the Thread Pool should be beneficial.

To learn more, see Section 7.6.3.4, “Thread Pool Tuning”.

A.15.5 Are there recommended Thread Pool configurations?

The Thread Pool has a number of user case driven configuration parameters that affect its performance. To learn about these and tips on tuning, see Section 7.6.3.4, “Thread Pool Tuning”.

A.16 MySQL 8.4 FAQ: InnoDB Change Buffer

A.16.1 What types of operations modify secondary indexes and result in change buffering? ............ 5414
A.16.2 What is the benefit of the InnoDB change buffer? ...................................................... 5414
A.16.3 Does the change buffer support other types of indexes? ........................................... 5414
A.16.4 How much space does InnoDB use for the change buffer? ..................................... 5414
A.16.5 How do I determine the current size of the change buffer? .................................... 5414
A.16.6 When does change buffer merging occur? ............................................................. 5414
MySQL 8.4 FAQ: InnoDB Change Buffer

A.16.1 What types of operations modify secondary indexes and result in change buffering?

`INSERT`, `UPDATE`, and `DELETE` operations can modify secondary indexes. If an affected index page is not in the buffer pool, the changes can be buffered in the change buffer.

A.16.2 What is the benefit of the InnoDB change buffer?

Buffering secondary index changes when secondary index pages are not in the buffer pool avoids expensive random access I/O operations that would be required to immediately read in affected index pages from disk. Buffered changes can be applied later, in batches, as pages are read into the buffer pool by other read operations.

A.16.3 Does the change buffer support other types of indexes?

No. The change buffer only supports secondary indexes. Clustered indexes, full-text indexes, and spatial indexes are not supported. Full-text indexes have their own caching mechanism.

A.16.4 How much space does InnoDB use for the change buffer?

Prior to the introduction of the `innodb_change_buffer_max_size` configuration option in MySQL 5.6, the maximum size of the on-disk change buffer in the system tablespace was 1/3 of the InnoDB buffer pool size.

In MySQL 5.6 and later, the `innodb_change_buffer_max_size` configuration option defines the maximum size of the change buffer as a percentage of the total buffer pool size. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

InnoDB does not buffer an operation if it would cause the on-disk change buffer to exceed the defined limit.

Change buffer pages are not required to persist in the buffer pool and may be evicted by LRU operations.

A.16.5 How do I determine the current size of the change buffer?

The current size of the change buffer is reported by `SHOW ENGINE INNODB STATUS \G`, under the `INSERT BUFFER AND ADAPTIVE HASH INDEX` heading. For example:

```
-------------------------------------
INSERT BUFFER AND ADAPTIVE HASH INDEX
-------------------------------------
Ibuf: size 1, free list len 0, seg size 2, 0 merges
```

Relevant data points include:

- `size`: The number of pages used within the change buffer. Change buffer size is equal to `seg size - (1 + free list len)`. The `1 +` value represents the change buffer header page.
- `seg size`: The size of the change buffer, in pages.

For information about monitoring change buffer status, see Section 17.5.2, “Change Buffer”.

A.16.6 When does change buffer merging occur?

---

5414
MySQL 8.4 FAQ: InnoDB Data-at-Rest Encryption

- When a page is read into the buffer pool, buffered changes are merged upon completion of the read, before the page is made available.

- Change buffer merging is performed as a background task. The `innodb_io_capacity` parameter sets an upper limit on the I/O activity performed by InnoDB background tasks such as merging data from the change buffer.

- A change buffer merge is performed during crash recovery. Changes are applied from the change buffer (in the system tablespace) to leaf pages of secondary indexes as index pages are read into the buffer pool.

- The change buffer is fully durable and can survive a system crash. Upon restart, change buffer merge operations resume as part of normal operations.

- A full merge of the change buffer can be forced as part of a slow server shutdown using `--innodb-fast-shutdown=0`.

**A.16.7** When is the change buffer flushed?

Updated pages are flushed by the same flushing mechanism that flushes the other pages that occupy the buffer pool.

**A.16.8** When should the change buffer be used?

The change buffer is a feature designed to reduce random I/O to secondary indexes as indexes grow larger and no longer fit in the InnoDB buffer pool. Generally, the change buffer should be used when the entire data set does not fit into the buffer pool, when there is substantial DML activity that modifies secondary index pages, or when there are lots of secondary indexes that are regularly changed by DML activity.

**A.16.9** When should the change buffer not be used?

You might consider disabling the change buffer if the entire data set fits within the InnoDB buffer pool, if you have relatively few secondary indexes, or if you are using solid-state storage, where random reads are about as fast as sequential reads. Before making configuration changes, it is recommended that you run tests using a representative workload to determine if disabling the change buffer provides any benefit.

**A.16.10** Where can I find additional information about the change buffer?

See Section 17.5.2, “Change Buffer”.

### A.17 MySQL 8.4 FAQ: InnoDB Data-at-Rest Encryption

- **A.17.1** Is data decrypted for users who are authorized to see it? ................................................................. 5416

- **A.17.4** Is it possible to use 3rd party encryption algorithms in place of the one provided by the InnoDB data-at-rest encryption feature? ................................................................. 5416
- **A.17.5** Can indexed columns be encrypted? .................................................................................................. 5416
- **A.17.6** What data types and data lengths does InnoDB data-at-rest encryption support? .............. 5416
- **A.17.7** Does data remain encrypted on the network? ................................................................................. 5416
- **A.17.8** Does database memory contain cleartext or encrypted data? ......................................................... 5416
- **A.17.9** How do I know which data to encrypt? .......................................................................................... 5416
- **A.17.10** How is InnoDB data-at-rest encryption different from encryption functions MySQL already provides? ................................................................. 5417
A.17.11 Does the transportable tablespaces feature work with InnoDB data-at-rest encryption? .......... 5417
A.17.12 Does compression work with InnoDB data-at-rest encryption? ........................................ 5417
A.17.13 Can I use mysqldump with encrypted tables? ................................................................. 5417
A.17.14 How do I change (rotate, re-key) the master encryption key? ............................................ 5417
A.17.15 How do I migrate data from a cleartext InnoDB tablespace to an encrypted InnoDB tablespace? ........................................................................................................................................ 5417

A.17.1 Is data decrypted for users who are authorized to see it?

Yes. InnoDB data-at-rest encryption is designed to transparently apply encryption within the database without impacting existing applications. Returning data in encrypted format would break most existing applications. InnoDB data-at-rest encryption provides the benefit of encryption without the overhead associated with traditional database encryption solutions, which would typically require expensive and substantial changes to applications, database triggers, and views.

A.17.2 What is the overhead associated with InnoDB data-at-rest encryption?

There is no additional storage overhead. According to internal benchmarks, performance overhead amounts to a single digit percentage difference.

A.17.3 What are the encryption algorithms used with InnoDB data-at-rest encryption?

InnoDB data-at-rest encryption supports the Advanced Encryption Standard (AES256) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

A.17.4 Is it possible to use 3rd party encryption algorithms in place of the one provided by the InnoDB data-at-rest encryption feature?

No, it is not possible to use other encryption algorithms. The provided encryption algorithm is broadly accepted.

A.17.5 Can indexed columns be encrypted?

InnoDB data-at-rest encryption supports all indexes transparently.

A.17.6 What data types and data lengths does InnoDB data-at-rest encryption support?

InnoDB data-at-rest encryption supports all supported data types. There is no data length limitation.

A.17.7 Does data remain encrypted on the network?

Data encrypted by the InnoDB data-at-rest feature is decrypted when it is read from the tablespace file. Thus, if the data is on the network, it is in cleartext form. However, data on the network can be encrypted using MySQL network encryption, which encrypts data traveling to and from a database using SSL/TLS.

A.17.8 Does database memory contain cleartext or encrypted data?

With InnoDB data-at-rest encryption, in-memory data is decrypted, which provides complete transparency.

A.17.9 How do I know which data to encrypt?

Compliance with the PCI-DSS standard requires that credit card numbers (Primary Account Number, or 'PAN') be stored in encrypted form. Breach Notification Laws (for example, CA SB 1386, CA AB 1950, and similar laws in 43+ more US states) require encryption of first name, last name,
driver license number, and other PII data. In early 2008, CA AB 1298 added medical and health
insurance information to PII data. Additionally, industry specific privacy and security standards may
require encryption of certain assets. For example, assets such as pharmaceutical research results,
oil field exploration results, financial contracts, or personal data of law enforcement informants may
require encryption. In the health care industry, the privacy of patient data, health records and X-ray
images is of the highest importance.

**A.17.10. How is InnoDB data-at-rest encryption different from encryption functions MySQL already provides?**

There are symmetric and asymmetric encryption APIs in MySQL that can be used to manually
encrypt data within the database. However, the application must manage encryption keys and
perform required encryption and decryption operations by calling API functions. InnoDB data-at-rest
encryption requires no application changes, is transparent to end users, and provides automated,
built-in key management.

**A.17.11. Does the transportable tablespaces feature work with InnoDB data-at-rest encryption?**

Yes. It is supported for encrypted file-per-table tablespaces. For more information, see Exporting
Encrypted Tablespaces.

**A.17.12. Does compression work with InnoDB data-at-rest encryption?**

Customers using InnoDB data-at-rest encryption receive the full benefit of compression because
compression is applied before data blocks are encrypted.

**A.17.13. Can I use mysqldump with encrypted tables?**

Yes. Because these utilities create logical backups, the data dumped from encrypted tables is not
encrypted.

**A.17.14. How do I change (rotate, re-key) the master encryption key?**

InnoDB data-at-rest encryption uses a two tier key mechanism. When data-at-rest encryption is
used, individual tablespace keys are stored in the header of the underlying tablespace data file.
Tablespace keys are encrypted using the master encryption key. The master encryption key is
generated when tablespace encryption is enabled, and is stored outside the database. The master
encryption key is rotated using the `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement,
which generates a new master encryption key, stores the key, and rotates the key into use.

**A.17.15. How do I migrate data from a cleartext InnoDB tablespace to an encrypted InnoDB tablespace?**

Transferring data from one tablespace to another is not required. To encrypt data in an InnoDB file-
per-table tablespace, run `ALTER TABLE tbl_name ENCRYPTION = 'Y'`. To encrypt a general
tablespace or the mysql tablespace, run `ALTER TABLESPACE tablespace_name ENCRYPTION
= 'Y'`. Encryption support for general tablespaces was introduced in MySQL 8.0.13. Encryption
support for the mysql system tablespace is available as of MySQL 8.0.16.

**A.18 MySQL 8.4 FAQ: Virtualization Support**

**A.18.1 Is MySQL supported on virtualized environments such as Oracle VM, VMWare, Docker,
Microsoft Hyper-V, or others?**

MySQL is supported on virtualized environments, but is certified only for Oracle VM. Contact Oracle
Support for more information.
Be aware of potential problems when using virtualization software. The usual ones are related to performance, performance degradations, slowness, or unpredictability of disk, I/O, network, and memory.

This appendix describes the types of error information MySQL provides and how to obtain information about them. The final section is for troubleshooting. It describes common problems and errors that may occur and potential resolutions.

Additional Resources

Other error-related documentation includes:

- Information about configuring where and how the server writes the error log: Section 7.4.2, “The Error Log”
- Information about the character set used for error messages: Section 12.6, “Error Message Character Set”
- Information about the language used for error messages: Section 12.12, “Setting the Error Message Language”
- Information about errors related to InnoDB: Section 17.20.5, “InnoDB Error Handling”
- Information about errors specific to NDB Cluster: NDB Cluster API Errors; see also NDB API Errors and Error Handling, and MGM API Errors
- Descriptions of the error messages that the MySQL server and client programs generate: MySQL 8.4 Error Message Reference

B.1 Error Message Sources and Elements

This section discusses how error messages originate within MySQL and the elements they contain.

- Error Message Sources
- Error Message Elements
- Error Code Ranges

Error Message Sources

Error messages can originate on the server side or the client side:
• On the server side, error messages may occur during the startup and shutdown processes, as a result of issues that occur during SQL statement execution, and so forth.

• The MySQL server writes some error messages to its error log. These indicate issues of interest to database administrators or that require DBA action.

• The server sends other error messages to client programs. These indicate issues pertaining only to a particular client. The MySQL client library takes errors received from the server and makes them available to the host client program.

• Client-side error messages are generated from within the MySQL client library, usually involving problems communicating with the server.

Example server-side error messages written to the error log:

• This message produced during the startup process provides a status or progress indicator:

  2018-10-28T13:01:32.735983Z 0 [Note] [MY-010303] [Server] Skipping generation of SSL certificates as options related to SSL are specified.

• This message indicates an issue that requires DBA action:

  2018-10-02T03:20:39.410387Z 768 [ERROR] [MY-010045] [Server] Event Scheduler: [evtuser@localhost][myschema.e_daily] Unknown database 'mydb'

Example server-side error message sent to client programs, as displayed by the `mysql` client:

```
mysql> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Example client-side error message originating from within the client library, as displayed by the `mysql` client:

```
$> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (-2)
```

Whether an error originates from within the client library or is received from the server, a MySQL client program may respond in varying ways. As just illustrated, the client may display the error message so the user can take corrective measures. The client may instead internally attempt to resolve or retry a failed operation, or take other action.

**Error Message Elements**

When an error occurs, error information includes several elements: an error code, SQLSTATE value, and message string. These elements have the following characteristics:

• Error code: This value is numeric. It is MySQL-specific and is not portable to other database systems.

  Each error number has a corresponding symbolic value. Examples:

  • The symbol for server error number 1146 is **ER_NO_SUCH_TABLE**.
  
  • The symbol for client error number 2005 is **CR_UNKNOWN_HOST**.

  The set of error codes used in error messages is partitioned into distinct ranges; see [Error Code Ranges](#).

  Error codes are stable across General Availability (GA) releases of a given MySQL series. Before a series reaches GA status, new codes may still be under development and are subject to change.
• SQLSTATE value: This value is a five-character string (for example, '42S02'). SQLSTATE values are taken from ANSI SQL and ODBC and are more standardized than the numeric error codes. The first two characters of an SQLSTATE value indicate the error class:
  • Class = '00' indicates success.
  • Class = '01' indicates a warning.
  • Class = '02' indicates "not found." This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
  • Class > '02' indicates an exception.

For server-side errors, not all MySQL error numbers have corresponding SQLSTATE values. In these cases, 'HY000' (general error) is used.

For client-side errors, the SQLSTATE value is always 'HY000' (general error), so it is not meaningful for distinguishing one client error from another.

• Message string: This string provides a textual description of the error.

Error Code Ranges

The set of error codes used in error messages is partitioned into distinct ranges, each with its own purpose:

• 1 to 999: Global error codes. This error code range is called "global" because it is a shared range that is used by the server as well as by clients.

  When an error in this range originates on the server side, the server writes it to the error log, padding the error code with leading zeros to six digits and adding a prefix of `MY-`.

  When an error in this range originates on the client side, the client library makes it available to the client program with no zero-padding or prefix.

• 1,000 to 1,999: Server error codes reserved for messages sent to clients.

• 2,000 to 2,999: Client error codes reserved for use by the client library.

• 3,000 to 4,999: Server error codes reserved for messages sent to clients.

• 5,000 to 5,999: Error codes reserved for use by X Plugin for messages sent to clients.

• 10,000 to 49,999: Server error codes reserved for messages to be written to the error log (not sent to clients).

  When an error in this range occurs, the server writes it to the error log, padding the error code with leading zeros to six digits and adding a prefix of `MY-`.

• 50,000 to 51,999: Error codes reserved for use by third parties.

The server handles error messages written to the error log differently from error messages sent to clients:

• When the server writes a message to the error log, it pads the error code with leading zeros to six digits and adds a prefix of `MY-` (examples: `MY-000022, MY-010048`).

• When the server sends a message to a client program, it adds no zero-padding or prefix to the error code (examples: `1036, 3013`).
B.2 Error Information Interfaces

Error messages can originate on the server side or the client side, and each error message includes an error code, SQLSTATE value, and message string, as described in Section B.1, “Error Message Sources and Elements”. For lists of server-side, client-side, and global (shared between server and clients) errors, see MySQL 8.4 Error Message Reference.

For error checking from within programs, use error code numbers or symbols, not error message strings. Message strings do not change often, but it is possible. Also, if the database administrator changes the language setting, that affects the language of message strings; see Section 12.12, “Setting the Error Message Language”.

Error information in MySQL is available in the server error log, at the SQL level, from within client programs, and at the command line.

- Error Log
- SQL Error Message Interface
- Client Error Message Interface
- Command-Line Error Message Interface

Error Log

On the server side, some messages are intended for the error log. For information about configuring where and how the server writes the log, see Section 7.4.2, “The Error Log”.

Other server error messages are intended to be sent to client programs and are available as described in Client Error Message Interface.

The range within which a particular error code lies determines whether the server writes an error message to the error log or sends it to clients. For information about these ranges, see Error Code Ranges.

SQL Error Message Interface

At the SQL level, there are several sources of error information in MySQL:

- SQL statement warning and error information is available through the SHOW WARNINGS and SHOW ERRORS statements. The warning_count system variable indicates the number of errors, warnings, and notes (with notes excluded if the sql_notes system variable is disabled). The error_count system variable indicates the number of errors. Its value excludes warnings and notes.

- The GET DIAGNOSTICS statement may be used to inspect the diagnostic information in the diagnostics area. See Section 15.6.7.3, "GET DIAGNOSTICS Statement".

- SHOW REPLICA STATUS statement output includes information about replication errors occurring on replica servers.

- SHOW ENGINE INNODB STATUS statement output includes information about the most recent foreign key error if a CREATE TABLE statement for an InnoDB table fails.

Client Error Message Interface

Client programs receive errors from two sources:

- Errors that originate on the client side from within the MySQL client library.
Errors that originate on the server side and are sent to the client by the server. These are received within
the client library, which makes them available to the host client program.

The range within which a particular error code lies determines whether it originated from within the client
library or was received by the client from the server. For information about these ranges, see Error Code
Ranges.

Regardless of whether an error originates from within the client library or is received from the server,
a MySQL client program obtains the error code, SQLSTATE value, message string, and other related
information by calling C API functions in the client library:

- `mysql_errno()` returns the MySQL error code.
- `mysql_sqlstate()` returns the SQLSTATE value.
- `mysql_error()` returns the message string.
- `mysql_stmt_errno()`, `mysql_stmt_sqlstate()`, and `mysql_stmt_error()` are the
corresponding error functions for prepared statements.
- `mysql_warning_count()` returns the number of errors, warnings, and notes for the most recent
  statement.

For descriptions of the client library error functions, see MySQL 8.4 C API Developer Guide.

A MySQL client program may respond to an error in varying ways. The client may display the error
message so the user can take corrective measures, internally attempt to resolve or retry a failed operation,
or take other action. For example, (using the `mysql` client), a failure to connect to the server might result in
this message:

```
$> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (-2)
```

**Command-Line Error Message Interface**

The `perror` program provides information from the command line about error numbers. See Section 6.8.1,
“perror — Display MySQL Error Message Information”.

```
$> perror 1231
MySQL error code MY-001231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s'
can't be set to the value of '%-.200s'
```

For MySQL NDB Cluster errors, use `ndb_perror`. See Section 25.5.16, “ndb_perror — Obtain NDB Error
Message Information”.

```
$> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing:
Permanent error: Application error
```

**B.3 Problems and Common Errors**

This section lists some common problems and error messages that you may encounter. It describes how to
determine the causes of the problems and what to do to solve them.

**B.3.1 How to Determine What Is Causing a Problem**

When you run into a problem, the first thing you should do is to find out which program or piece of
equipment is causing it:
• If you have one of the following symptoms, then it is probably a hardware problem (such as memory, motherboard, CPU, or hard disk) or kernel problem:

• The keyboard does not work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light does not change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)

• The mouse pointer does not move.

• The machine does not answer to a remote machine's pings.

• Other programs that are not related to MySQL do not behave correctly.

• Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as glibc) are up to date.

It is always good to use a machine with ECC memory to discover memory problems early.

• If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing kbd_mode -a.

• Please examine your system log file (/var/log/messages or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL’s log files. See Section 7.4, “MySQL Server Logs”.

• If you do not think you have hardware problems, you should try to find out which program is causing problems. Try using top, ps, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.

• Use top, df, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.

• If the problem is some runaway process, you can always try to kill it. If it does not want to die, there is probably a bug in the operating system.

If you have examined all other possibilities and concluded that the MySQL server or a MySQL client is causing the problem, it is time to create a bug report, see Section 1.6, “How to Report Bugs or Problems”. In the bug report, try to give a complete description of how the system is behaving and what you think is happening. Also state why you think that MySQL is causing the problem. Take into consideration all the situations described in this chapter. State any problems exactly how they appear when you examine your system. Use the “copy and paste” method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only “the system does not work.” This provides us with no information about what could be the problem.

If a program fails, it is always useful to know the following information:

• Has the program in question made a segmentation fault (did it dump core)?

• Is the program taking up all available CPU time? Check with top. Let the program run for a while, it may simply be evaluating something computationally intensive.
• If the `mysqld` server is causing problems, can you get any response from it with `mysqladmin -u root ping` or `mysqladmin -u root processlist`?

• What does a client program say when you try to connect to the MySQL server? (Try with `mysql`, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in Section 1.6, “How to Report Bugs or Problems”.

**B.3.2 Common Errors When Using MySQL Programs**

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

**B.3.2.1 Access denied**

An *Access denied* error can have many causes. Often the problem is related to the MySQL accounts that the server permits client programs to use when connecting. See Section 8.2, “Access Control and Account Management”, and Section 8.2.22, “Troubleshooting Problems Connecting to MySQL”.

**B.3.2.2 Can't connect to [local] MySQL server**

A MySQL client on Unix can connect to the `mysqld` server in two different ways: By using a Unix socket file to connect through a file in the file system (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you do not specify a host name or if you specify the special host name `localhost`

If the MySQL server is running on Windows, you can connect using TCP/IP. If the server is started with the `named_pipe` system variable enabled, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is `MySQL` by default. If you do not give a host name when connecting to `mysqld`, a MySQL client first tries to connect to the named pipe. If that does not work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using `.` as the host name.

The error (2002) *Can’t connect to ...* normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket file name or TCP/IP port number when trying to connect to the server. You should also check that the TCP/IP port you are using has not been blocked by a firewall or port blocking service.

The error (2003) *Can’t connect to MySQL server on 'server' (10061)* indicates that the network connection has been refused. You should check that there is a MySQL server running, that it has network connections enabled, and that the network port you specified is the one configured on the server.

Start by checking whether there is a process named `mysqld` running on your server host. (Use `ps xa | grep mysqld` on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See Section 2.9.2, “Starting the Server”.

If a `mysqld` process is running, you can check it by trying the following commands. The port number or Unix socket file name might be different in your setup. `host_ip` represents the IP address of the machine where the server is running.

```
$> mysqladmin version
$> mysqladmin variables
$> mysqladmin -h `hostname` version variables
```
**Common Errors When Using MySQL Programs**

Note the use of backticks rather than forward quotation marks with the `hostname` command; these cause the output of `hostname` (that is, the current host name) to be substituted into the `mysqladmin` command. If you have no `hostname` command or are running on Windows, you can manually type the host name of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with the `skip_networking` system variable enabled, it cannot accept TCP/IP connections at all. If the server was started with the `bind_address` system variable set to `127.0.0.1`, it listens for TCP/IP connections only locally on the loopback interface and does not accept remote connections.

Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.

Here are some reasons the **Can't connect to local MySQL server** error might occur:

- **mysqld** is not running on the local host. Check your operating system’s process list to ensure the `mysqld` process is present.

- You’re running a MySQL server on Windows with many TCP/IP connections to it. If you’re experiencing that quite often your clients get that error, you can find a workaround here: [Connection to MySQL Server Failing on Windows](#).

- Someone has removed the Unix socket file that `mysqld` uses (`/tmp/mysql.sock` by default). For example, you might have a cron job that removes old files from the `/tmp` directory. You can always run `mysqladmin version` to check whether the Unix socket file that `mysqladmin` is trying to use really exists. The fix in this case is to change the cron job to not remove `mysql.sock` or to place the socket file somewhere else. See [Section B.3.3.6, “How to Protect or Change the MySQL Unix Socket File”](#).

- You have started the `mysqld` server with the `--socket=/path/to/socket` option, but forgotten to tell client programs the new name of the socket file. If you change the socket path name for the server, you must also notify the MySQL clients. You can do this by providing the same `--socket` option when you run client programs. You also need to ensure that clients have permission to access the `mysql.sock` file. To find out where the socket file is, you can do:

  ```
  $> netstat -ln | grep mysql
  ```

  See [Section B.3.3.6, “How to Protect or Change the MySQL Unix Socket File”](#).

- You are using Linux and one server thread has died (dumped core). In this case, you must kill the other `mysqld` threads (for example, with `kill`) before you can restart the MySQL server. See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).

- The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access privileges for the directory or socket file so that the server and clients can access them, or restart `mysqld` with a `--socket` option that specifies a socket file name in a directory where the server can create it and where client programs can access it.
If you get the error message *Can't connect to MySQL server on some_host*, you can try the following things to find out what the problem is:

- Check whether the server is running on that host by executing `telnet some_host 3306` and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server's version number. If you get an error such as *telnet: Unable to connect to remote host: Connection refused*, then there is no server running on the given port.

- If the server is running on the local host, try using `mysqladmin -h localhost variables` to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the `port` variable.)

- If you are running under Linux and Security-Enhanced Linux (SELinux) is enabled, see Section 8.7, “SELinux”.

**Connection to MySQL Server Failing on Windows**

When you're running a MySQL server on Windows with many TCP/IP connections to it, and you're experiencing that quite often your clients get a *Can't connect to MySQL server* error, the reason might be that Windows does not allow for enough ephemeral (short-lived) ports to serve those connections.

The purpose of `TIME_WAIT` is to keep a connection accepting packets even after the connection has been closed. This is because Internet routing can cause a packet to take a slow route to its destination and it may arrive after both sides have agreed to close. If the port is in use for a new connection, that packet from the old connection could break the protocol or compromise personal information from the original connection. The `TIME_WAIT` delay prevents this by ensuring that the port cannot be reused until after some time has been permitted for those delayed packets to arrive.

It is safe to reduce `TIME_WAIT` greatly on LAN connections because there is little chance of packets arriving at very long delays, as they could through the Internet with its comparatively large distances and latencies.

Windows permits ephemeral (short-lived) TCP ports to the user. After any port is closed, it remains in a `TIME_WAIT` status for 120 seconds. The port is not available again until this time expires. The default range of port numbers depends on the version of Windows, with a more limited number of ports in older versions:

- Windows through Server 2003: Ports in range 1025–5000

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the `TIME_WAIT` status you have a good chance for running out of ports. There are two ways to address this problem:

- Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible
- Tune some settings in the Windows registry (see below)

**Important**

The following procedure involves modifying the Windows registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore it if a problem occurs. For information about how to back up, restore,
and edit the registry, view the following article in the Microsoft Knowledge Base: http://support.microsoft.com/kb/256986/EN-US/.

1. Start Registry Editor (Regedt32.exe).

2. Locate the following key in the registry:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters
```

3. On the Edit menu, click Add Value, and then add the following registry value:

```
Value Name: MaxUserPort
Data Type: REG_DWORD
Value: 65534
```

This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).

4. On the Edit menu, click Add Value, and then add the following registry value:

```
Value Name: TcpTimedWaitDelay
Data Type: REG_DWORD
Value: 30
```

This sets the number of seconds to hold a TCP port connection in TIME_WAIT state before closing. The valid range is between 30 and 300 decimal, although you may wish to check with Microsoft for the latest permitted values. The default value is 0x78 (120 decimal).

5. Quit Registry Editor.

6. Reboot the machine.

Note: Undoing the above should be as simple as deleting the registry entries you've created.

**B.3.2.3 Lost connection to MySQL server**

There are three likely causes for this error message.

Usually it indicates network connectivity trouble and you should check the condition of your network if this error occurs frequently. If the error message includes “during query,” this is probably the case you are experiencing.

Sometimes the “during query” form happens when millions of rows are being sent as part of one or more queries. If you know that this is happening, you should try increasing net_read_timeout from its default of 30 seconds to 60 seconds or longer, sufficient for the data transfer to complete.

More rarely, it can happen when the client is attempting the initial connection to the server. In this case, if your connect_timeout value is set to only a few seconds, you may be able to resolve the problem by increasing it to ten seconds, perhaps more if you have a very long distance or slow connection. You can determine whether you are experiencing this more uncommon cause by using SHOW GLOBAL STATUS LIKE 'Aborted_connects'. It increases by one for each initial connection attempt that the server aborts. You may see “reading authorization packet” as part of the error message; if so, that also suggests that this is the solution that you need.

If the cause is none of those just described, you may be experiencing a problem with BLOB values that are larger than max_allowed_packet, which can cause this error with some clients. Sometime you may see an ER_NET_PACKET_TOO_LARGE error, and that confirms that you need to increase max_allowed_packet.
B.3.2.4 Password Fails When Entered Interactively

MySQL client programs prompt for a password when invoked with a `--password` or `-p` option that has no following password value:

```
$> mysql -u user_name -p
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the `Enter password:` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

B.3.2.5 Too many connections

If clients encounter `Too many connections` errors when attempting to connect to the `mysqld` server, all available connections are in use by other clients.

The permitted number of connections is controlled by the `max_connections` system variable. To support more connections, set `max_connections` to a larger value.

`mysqld` actually permits `max_connections + 1` client connections. The extra connection is reserved for use by accounts that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). By granting the privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 15.7.7.30, “SHOW PROCESSLIST Statement”.

The server also permits administrative connections on a dedicated interface. For more information about how the server handles client connections, see Section 7.1.12.1, “Connection Interfaces”.

B.3.2.6 Out of memory

If you issue a query using the `mysql` client program and receive an error like the following one, it means that `mysql` does not have enough memory to store the entire query result:

```
mysql: Out of memory at line 42, 'malloc.c'
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke `mysql` with the `--quick` option. This causes it to use the `mysql_use_result()` C API function to retrieve the result set, which places less of a load on the client (but more on the server).

B.3.2.7 MySQL server has gone away

This section also covers the related `Lost connection to server during query` error.

The most common reason for the `MySQL server has gone away` error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent).

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR_SERVER_GONE_ERROR</td>
<td>The client couldn't send a question to the server.</td>
</tr>
</tbody>
</table>
Common Errors When Using MySQL Programs

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR_SERVER_LOST</td>
<td>The client didn’t get an error when writing to the server, but it didn’t get a full answer (or any answer) to the question.</td>
</tr>
</tbody>
</table>

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the `wait_timeout` variable when you start `mysqld`. See Section 7.1.8, "Server System Variables".

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the `mysql` command-line client).

Some other common reasons for the MySQL server has gone away error are:

- You (or the db administrator) has killed the running thread with a `KILL` statement or a `mysqladmin kill` command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.
- A client application running on a different host does not have the necessary privileges to connect to the MySQL server from that host.
- You got a timeout from the TCP/IP connection on the client side. This may happen if you have been using the commands: `mysql_options(...)`, `MYSQL_OPT_READ_TIMEOUT,...`) or `mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT,...)`. In this case increasing the timeout may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the `reconnect` flag in the `MYSQL` structure is equal to 0).
- You are using a Windows client and the server had dropped the connection (probably because `wait_timeout` expired) before the command was issued.

The problem on Windows is that in some cases MySQL does not get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from the connection.

The solution to this is to either do a `mysql_ping()` on the connection if there has been a long time since the last query (this is what Connector/ODBC does) or set `wait_timeout` on the `mysqld` server so high that it in practice never times out.

- You can also get these errors if you send a query to the server that is incorrect or too large. If `mysqld` receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big BLOB columns), you can increase the query limit by setting the server's `max_allowed_packet` variable, which has a default value of 64MB. You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in Section B.3.2.8, "Packet Too Large".

An `INSERT` or `REPLACE` statement that inserts a great many rows can also cause these sorts of errors. Either one of these statements sends a single request to the server irrespective of the number of rows to be inserted; thus, you can often avoid the error by reducing the number of rows sent per `INSERT` or `REPLACE`.

- It is also possible to see this error if host name lookups fail (for example, if the DNS server on which your server or network relies goes down). This is because MySQL is dependent on the host system for name
Common Errors When Using MySQL Programs

resolution, but has no way of knowing whether it is working—from MySQL's point of view the problem is
indistinguishable from any other network timeout.

You may also see the MySQL server has gone away error if MySQL is started with the
skip_networking system variable enabled.

Another networking issue that can cause this error occurs if the MySQL port (default 3306) is blocked by
your firewall, thus preventing any connections at all to the MySQL server.

• You can also encounter this error with applications that fork child processes, all of which try to use the
same connection to the MySQL server. This can be avoided by using a separate connection for each
child process.

• You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing mysqladmin version and
examining the server's uptime. If the client connection was broken because mysqld crashed and restarted,
you should concentrate on finding the reason for the crash. Start by checking whether issuing the query
again kills the server again. See Section B.3.3.3, "What to Do If MySQL Keeps Crashing".

You can obtain more information about lost connections by starting mysqld with the
log_error_verbosity system variable set to 3. This logs some of the disconnection messages in the
hostname.err file. See Section 7.4.2, "The Error Log".

If you want to create a bug report regarding this problem, be sure that you include the following
information:

• Indicate whether the MySQL server died. You can find information about this in the server error log. See
Section B.3.3.3, "What to Do If MySQL Keeps Crashing".

• If a specific query kills mysqld and the tables involved were checked with CHECK TABLE before you ran
the query, can you provide a reproducible test case? See Section 7.9, "Debugging MySQL".

• What is the value of the wait_timeout system variable in the MySQL server? (mysqladmin
variables gives you the value of this variable.)

• Have you tried to run mysqld with the general query log enabled to determine whether the problem
query appears in the log? (See Section 7.4.3, "The General Query Log".)

See also Section B.3.2.9, "Communication Errors and Aborted Connections", and Section 1.6, "How to
Report Bugs or Problems".

B.3.2.8 Packet Too Large

A communication packet is a single SQL statement sent to the MySQL server, a single row that is sent to
the client, or a binary log event sent from a replication source server to a replica.

The largest possible packet that can be transmitted to or from a MySQL 8.4 server or client is 1GB.

When a MySQL client or the mysqld server receives a packet bigger than max_allowed_packet bytes,
it issues an ER_NET_PACKET_TOO_LARGE error and closes the connection. With some clients, you may
also get a Lost connection to MySQL server during query error if the communication packet is
too large.

Both the client and the server have their own max_allowed_packet variable, so if you want to handle big
packets, you must increase this variable both in the client and in the server.
If you are using the `mysql` client program, its default `max_allowed_packet` variable is 16MB. To set a larger value, start `mysql` like this:

```
$> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` value is 64MB. You can increase this if the server needs to handle big queries (for example, if you are working with big BLOB columns). For example, to set the variable to 128MB, start the server like this:

```
$> mysqld --max_allowed_packet=128M
```

You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 128MB, add the following lines in an option file:

```
[mysqld]
max_allowed_packet=128M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large BLOB values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

### B.3.2.9 Communication Errors and Aborted Connections

If connection problems occur such as communication errors or aborted connections, use these sources of information to diagnose problems:

- The error log. See Section 7.4.2, “The Error Log”.
- The general query log. See Section 7.4.3, “The General Query Log”.
- The `Aborted_`xxx and `Connection_errors_`xxx status variables. See Section 7.1.10, “Server Status Variables”.
- The host cache, which is accessible using the Performance Schema `host_cache` table. See Section 7.1.12.3, “DNS Lookups and the Host Cache”, and Section 29.12.22.3, “The host_cache Table”.

If the `log_error_verbosity` system variable is set to 3, you might find messages like this in your error log:

```
[Note] Aborted connection 854 to db: 'employees' user: 'josh'
```

If a client is unable even to connect, the server increments the `Aborted_connects` status variable. Unsuccessful connection attempts can occur for the following reasons:

- A client attempts to access a database but has no privileges for it.
- A client uses an incorrect password.
- A connection packet does not contain the right information.
- It takes more than `connect_timeout` seconds to obtain a connect packet. See Section 7.1.8, “Server System Variables”.
If these kinds of things happen, it might indicate that someone is trying to break into your server! If the general query log is enabled, messages for these types of problems are logged to it.

If a client successfully connects but later disconnects improperly or is terminated, the server increments the `Aborted_clients` status variable, and logs an `Aborted connection` message to the error log. The cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
- The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See Section 7.1.8, “Server System Variables”.
- The client program ended abruptly in the middle of a data transfer.

Other reasons for problems with aborted connections or aborted clients:

- The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for `mysqld`. See Section B.3.2.8, “Packet Too Large”.
- Use of Ethernet protocol with Linux, both half and full duplex. Some Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file using FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. Switch the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and test the results to determine the best setting.
- A problem with the thread library that causes interrupts on reads.
- Badly configured TCP/IP.
- Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

See also Section B.3.2.7, “MySQL server has gone away”.

### B.3.2.10 The table is full

If a table-full error occurs, it may be that the disk is full or that the table has reached its maximum size. The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. See Section 10.4.6, “Limits on Table Size”.

### B.3.2.11 Can't create/write to file

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysql` with the `--tmpdir` option or to add the option to the `[mysqld]` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```ini
[mysqld]
tmpdir=C:\temp
```

The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See Section 6.2.2.2, “Using Option Files”.

5433
Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` directory.

Check also the error code that you get with `perror`. One reason the server cannot write to a table is that the file system is full:

```
$> perror 28
OS error code  28:  No space left on device
```

If you get an error of the following type during startup, it indicates that the file system or directory used for storing data files is write protected. Provided that the write error is to a test file, the error is not serious and can be safely ignored.

```
Can't create test file /usr/local/mysql/data/master.lower-test
```

### B.3.2.12 Commands out of sync

If you get *Commands out of sync; you can't run this command now* in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

### B.3.2.13 Ignoring user

If you get the following error, it means that when `mysqld` was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

```
Found wrong password for user 'some_user'@'some_host'; ignoring user
```

As a result, the account is simply ignored by the permission system. To fix this problem, assign a new, valid password to the account.

### B.3.2.14 Table 'tbl_name' doesn't exist

If you get either of the following errors, it usually means that no table exists in the default database with the given name:

```
Table 'tbl_name' doesn't exist
Can't find file: 'tbl_name' (errno: 2)
```

In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case-sensitive if they are located on a file system that has case-sensitive file names.

- Even for file systems that are not case-sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with `SHOW TABLES`. See Section 15.7.7, "SHOW Statements".

### B.3.2.15 Can’t initialize character set

You might see an error like this if you have character set problems:

```
MySQL Connection Failed: Can't initialize character set charset_name
```
This error can have any of the following causes:

- The character set is a multibyte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running CMake with the `DDEFAULT_CHARSET=charset_name` option. See Section 2.8.7, “MySQL Source-Configuration Options”.

  All standard MySQL binaries are compiled with support for all multibyte character sets.

- The character set is a simple character set that is not compiled into `mysqld`, and the character set definition files are not in the place where the client expects to find them.

  In this case, you need to use one of the following methods to solve the problem:

    - Recompile the client with support for the character set. See Section 2.8.7, “MySQL Source-Configuration Options”.
    - Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.
    - Copy the character definition files to the path where the client expects them to be.

### B.3.2.16 File Not Found and Similar Errors

If you get `ERROR 'file_name' not found (errno: 23), Can't open file: file_name (errno: 24)`, or any other error with `errno 23` or `errno 24` from MySQL, it means that you have not allocated enough file descriptors for the MySQL server. You can use the `perror` utility to get a description of what the error number means:

```bash
$> perror 23
OS error code 23: File table overflow
$> perror 24
OS error code 24: Too many open files
$> perror 11
OS error code 11: Resource temporarily unavailable
```

The problem here is that `mysqld` is trying to keep open too many files simultaneously. You can either tell `mysqld` not to open so many files at once or increase the number of file descriptors available to `mysqld`.

To tell `mysqld` to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the `table_open_cache` system variable (the default value is 64). This may not entirely prevent running out of file descriptors because in some circumstances the server may attempt to extend the cache size temporarily, as described in Section 10.4.3.1, “How MySQL Opens and Closes Tables”. Reducing the value of `max_connections` also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to `mysqld`, you can use the `--open-files-limit` option to `mysql_safe` or set the `open_files_limit` system variable. See Section 7.1.8, “Server System Variables”. The easiest way to set these values is to add an option to your option file. See Section 6.2.2.2, “Using Option Files”. If you have an old version of `mysql` that does not support setting the open files limit, you can edit the `mysql_safe` script. There is a commented-out line `ulimit -n 256` in the script. You can remove the `#` character to uncomment this line, and change the number 256 to set the number of file descriptors to be made available to `mysql`. `--open-files-limit` and `ulimit` can increase the number of file descriptors, but only up to the limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you start `mysql_safe` or `mysql` as `root` (just remember that you also need to start the server with the `--user` option in this case so that it does not continue to run as `root` after it starts up). If you need to
increase the operating system limit on the number of file descriptors available to each process, consult the documentation for your system.

Note
If you run the tcsh shell, ulimit does not work! tcsh also reports incorrect values when you ask for the current limits. In this case, you should start mysqld_safe using sh.

B.3.2.17 Table-Corruption Issues
If you have started mysqld with the myisam_recover_options system variable set, MySQL automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the hostname.err file 'Warning: Checking table ...' which is followed by Warning: Repairing table if the table needs to be repaired. If you get a lot of these errors, without mysqld having died unexpectedly just before, then something is wrong and needs to be investigated further.

When the server detects MyISAM table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: Got an error from thread_id=1, mi_dynrec.c:368. This is useful information to include in bug reports.

See also Section 7.1.7, “Server Command Options”, and Section 7.9.1.7, “Making a Test Case If You Experience Table Corruption”.

B.3.3 Administration-Related Issues
B.3.3.1 Problems with File Permissions
If you have problems with file permissions, the UMASK or UMASK_DIR environment variable might be set incorrectly when mysqld starts. For example, mysqld might issue the following error message when you create a table:

ERROR: Can't find file: 'path/with/file_name' (Errcode: 13)

The default UMASK and UMASK_DIR values are 0640 and 0750, respectively. mysqld assumes that the value for UMASK or UMASK_DIR is in octal if it starts with a zero. For example, setting UMASK=0600 is equivalent to UMASK=384 because 0600 octal is 384 decimal.

Assuming that you start mysqld using mysqld_safe, change the default UMASK value as follows:

UMASK=384 # = 600 in octal
export UMASK
mysqld_safe &

Note
An exception applies for the error log file if you start mysqld using mysqld_safe, which does not respect UMASK: mysqld_safe may create the error log file if it does not exist prior to starting mysqld, and mysqld_safe uses a umask set to a strict value of 0137. If this is unsuitable, create the error file manually with the desired access mode prior to executing mysqld_safe.

By default, mysqld creates database directories with an access permission value of 0750. To modify this behavior, set the UMASK_DIR variable. If you set its value, new directories are created with the combined UMASK and UMASK_DIR values. For example, to give group access to all new directories, start mysqld_safe as follows:

UMASK=384 # = 600 in octal
export UMASK
mysqld_safe &
### B.3.3.2 How to Reset the Root Password

If you have never assigned a root password for MySQL, the server does not require a password at all for connecting as root. However, this is insecure. For instructions on assigning a password, see Section 2.9.4, “Securing the Initial MySQL Account”.

If you know the root password and want to change it, see Section 15.7.1.1, “ALTER USER Statement”, and Section 15.7.1.10, “SET PASSWORD Statement”.

If you assigned a root password previously but have forgotten it, you can assign a new password. The following sections provide instructions for Windows and Unix and Unix-like systems, as well as generic instructions that apply to any system.

**Resetting the Root Password: Windows Systems**

On Windows, use the following procedure to reset the password for the MySQL 'root'@'localhost' account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

1. Log on to your system as Administrator.
2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list and stop it.
   
   If your server is not running as a service, you may need to use the Task Manager to force it to stop.
3. Create a text file containing the password-assignment statement on a single line. Replace the password with the password that you want to use.

   `ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass';`

4. Save the file. This example assumes that you name the file `C:\mysql-init.txt`.
5. Open a console window to get to the command prompt: From the Start menu, select Run, then enter `cmd` as the command to be run.
6. Start the MySQL server with the init_file system variable set to name the file (notice that the backslash in the option value is doubled):

   ```
   C:\> cd "C:\Program Files\MySQL\MySQL Server 8.4\bin"
   C:\> mysqld --init-file=C:\mysql-init.txt
   ```

   If you installed MySQL to a different location, adjust the cd command accordingly.

   The server executes the contents of the file named by the init_file system variable at startup, changing the 'root'@'localhost' account password.

   To have server output to appear in the console window rather than in a log file, add the --console option to the mysqld command.

   If you installed MySQL using the MySQL Installation Wizard, you may need to specify a --defaults-file option. For example:

   ```
   C:\> mysqld --defaults-file=C:\mysql.ini
   ```
Administration-Related Issues

The appropriate `--defaults-file` setting can be found using the Services Manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list, right-click it, and choose the Properties option. The Path to executable field contains the `--defaults-file` setting.

7. After the server has started successfully, delete C:\mysql-init.txt.

You should now be able to connect to the MySQL server as root using the new password. Stop the MySQL server and restart it normally. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.

Resetting the Root Password: Unix and Unix-Like Systems

On Unix, use the following procedure to reset the password for the MySQL 'root'@'localhost' account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

The instructions assume that you start the MySQL server from the Unix login account that you normally use for running it. For example, if you run the server using the mysql login account, you should log in as mysql before using the instructions. Alternatively, you can log in as root, but in this case you must start mysqld with the `--user=mysql` option. If you start the server as root without using `--user=mysql`, the server may create root-owned files in the data directory, such as log files, and these may cause permission-related problems for future server startups. If that happens, you must either change the ownership of the files to mysql or remove them.

1. Log on to your system as the Unix user that the MySQL server runs as (for example, mysql).

2. Stop the MySQL server if it is running. Locate the .pid file that contains the server's process ID. The exact location and name of this file depend on your distribution, host name, and configuration. Common locations are /var/lib/mysql/, /var/run/mysqld/, and /usr/local/mysql/data/. Generally, the file name has an extension of .pid and begins with either mysqld or your system's host name.

Stop the MySQL server by sending a normal `kill` (not `kill -9`) to the mysqld process. Use the actual path name of the .pid file in the following command:

```
$> kill `cat /mysql-data-directory/host_name.pid`
```

Use backticks (not forward quotation marks) with the cat command. These cause the output of cat to be substituted into the kill command.

3. Create a text file containing the password-assignment statement on a single line. Replace the password with the password that you want to use.

```
ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass';
```

4. Save the file. This example assumes that you name the file /home/me/mysql-init. The file contains the password, so do not save it where it can be read by other users. If you are not logged in as mysql (the user the server runs as), make sure that the file has permissions that permit mysql to read it.

5. Start the MySQL server with the init_file system variable set to name the file:

```
$> mysqld --init-file=/home/me/mysql-init &
```
The server executes the contents of the file named by the `init_file` system variable at startup, changing the 'root'@'localhost' account password.

Other options may be necessary as well, depending on how you normally start your server. For example, `--defaults-file` may be needed before the `init_file` argument.

6. After the server has started successfully, delete `/home/me/mysql-init`.

You should now be able to connect to the MySQL server as root using the new password. Stop the server and restart it normally.

### Resetting the Root Password: Generic Instructions

The preceding sections provide password-resetting instructions specifically for Windows and Unix and Unix-like systems. Alternatively, on any platform, you can reset the password using the `mysql` client (but this approach is less secure):

1. Stop the MySQL server if necessary, then restart it with the `--skip-grant-tables` option. This enables anyone to connect without a password and with all privileges, and disables account-management statements such as `ALTER USER` and `SET PASSWORD`. Because this is insecure, if the server is started with the `--skip-grant-tables` option, it also disables remote connections by enabling `skip_networking`.

2. Connect to the MySQL server using the `mysql` client; no password is necessary because the server was started with `--skip-grant-tables`:

   ```bash
   $> mysql
   ```

3. In the `mysql` client, tell the server to reload the grant tables so that account-management statements work:

   ```bash
   mysql> FLUSH PRIVILEGES;
   ```

   Then change the 'root'@'localhost' account password. Replace the password with the password that you want to use. To change the password for a root account with a different host name part, modify the instructions to use that host name.

   ```bash
   mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass';
   ```

   You should now be able to connect to the MySQL server as root using the new password. Stop the server and restart it normally (without the `--skip-grant-tables` option and without enabling the `skip_networking` system variable).

### B.3.3.3 What to Do If MySQL Keeps Crashing

Each MySQL version is tested on many platforms before it is released. This does not mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the `mysqld` server dies or whether your problem has to do with your client. You can check how long your `mysqld` server has been up by executing `mysqladmin version`. If `mysqld` has died and restarted, you may find the reason by looking in the server's error log. See Section 7.4.2, "The Error Log".

On some systems, you can find in the error log a stack trace of where `mysqld` died. Note that the variable values written in the error log may not always be 100% correct.
If you find that `mysqld` fails at startup during InnoDB recovery, refer to Section 17.20.2, “Troubleshooting Recovery Failures”.

Many unexpected server exits are caused by corrupted data files or index files. MySQL updates the files on disk with the `write()` system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with the `delay_key_write` system variable enabled, in which case data files are written but not index files.) This means that data file contents are safe even if `mysqld` crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting `mysqld` with the `--flush` option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in `mysqld` that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as `mysqld` without locking the table properly.
- You are running many `mysqld` servers using the same data directory on a system that does not support good file system locks (normally handled by the `lockd` lock manager), or you are running multiple servers with external locking disabled.
- You have a crashed data file or index file that contains very corrupt data that confused `mysqld`.
- You have found a bug in the data storage code. This isn't likely, but it is at least possible. In this case, you can try to change the storage engine to another engine by using `ALTER TABLE` on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others result in an unexpected exit for you. Try the following things:

- Stop the `mysqld` server with `mysqladmin shutdown`, run `myisamchk --silent --force */*.MYI` from the data directory to check all MyISAM tables, and restart `mysqld`. This ensures that you are running from a clean state. See Chapter 7, MySQL Server Administration.
- Start `mysqld` with the general query log enabled (see Section 7.4.3, “The General Query Log”). Then try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See Section 7.4.3, “The General Query Log”. If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have isolated the bug and should submit a bug report for it. See Section 1.6, “How to Report Bugs or Problems”.
- Try to make a test case that we can use to repeat the problem. See Section 7.9, “Debugging MySQL”.
- Try the `fork_big.pl` script. (It is located in the `tests` directory of source distributions.)
- Configuring MySQL for debugging makes it much easier to gather information about possible errors if something goes wrong. Reconfigure MySQL with the `--WITH_DEBUG=1` option to `CMake` and then recompile. See Section 7.9, “Debugging MySQL”.
- Make sure that you have applied the latest patches for your operating system.
- Use the `--skip-external-locking` option to `mysqld`. On some systems, the `lockd` lock manager does not work properly; the `--skip-external-locking` option tells `mysqld` not to use external...
locking. (This means that you cannot run two `mysqld` servers on the same data directory and that you must be careful if you use `myisamchk`. Nevertheless, it may be instructive to try the option as a test.)

- If `mysqld` appears to be running but not responding, try `mysqladmin -u root processlist`. Sometimes `mysqld` is not hung even though it seems unresponsive. The problem may be that all connections are in use, or there may be some internal lock problem. `mysqladmin -u root processlist` usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.

- Run the command `mysqladmin -i 5 status` or `mysqladmin -i 5 -r status` in a separate window to produce statistics while running other queries.

- Try the following:
  1. Start `mysqld` from `gdb` (or another debugger). See Section 7.9, “Debugging MySQL”.
  2. Run your test scripts.
  3. Print the backtrace and the local variables at the three lowest levels. In `gdb`, you can do this with the following commands when `mysqld` has crashed inside `gdb`:

```
backtrace
info local
up
info local
up
info local
```

With `gdb`, you can also examine which threads exist with `info threads` and switch to a specific thread with `thread N`, where `N` is the thread ID.

- Try to simulate your application with a Perl script to force MySQL to exit or misbehave.

- Send a normal bug report. See Section 1.6, “How to Report Bugs or Problems”. Be even more detailed than usual. Because MySQL works for many people, the crash might result from something that exists only on your computer (for example, an error that is related to your particular system libraries).

- If you have a problem with tables containing dynamic-length rows and you are using only `VARCHAR` columns (not `BLOB` or `TEXT` columns), you can try to change all `VARCHAR` to `CHAR` with `ALTER TABLE`. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

- Consider the possibility of hardware faults when diagnosing problems. Defective hardware can be the cause of data corruption. Pay particular attention to your memory and disk subsystems when troubleshooting hardware.

**B.3.3.4 How MySQL Handles a Full Disk**

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to `MyISAM` tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event.”

When a disk-full condition occurs, MySQL does the following:
• It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.

• Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, take the following actions:

• To continue, you only have to free enough disk space to insert all records.

• Alternatively, to abort the thread, use `mysqladmin kill`. The thread is aborted the next time it checks the disk (in one minute).

• Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition enables the other threads to continue.

Exceptions to the preceding behavior are when you use `REPAIR TABLE` or `OPTIMIZE TABLE` or when the indexes are created in a batch after `LOAD DATA` or after an `ALTER TABLE` statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for `ALTER TABLE`, the old table is left unchanged.

### B.3.3.5 Where MySQL Stores Temporary Files

On Unix, MySQL uses the value of the `TMPDIR` environment variable as the path name of the directory in which to store temporary files. If `TMPDIR` is not set, MySQL uses the system default, which is usually `/tmp`, `/var/tmp`, or `/usr/tmp`.

On Windows, MySQL checks in order the values of the `TMPDIR`, `TEMP`, and `TMP` environment variables. For the first one found to be set, MySQL uses it and does not check those remaining. If none of `TMPDIR`, `TEMP`, or `TMP` are set, MySQL uses the Windows system default, which is usually `C:\windows\temp\`.

If the file system containing your temporary file directory is too small, you can use the `mysqld --tmpdir` option to specify a directory in a file system where you have enough space.

The `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

**Note**

To spread the load effectively, these paths should be located on different physical disks, not different partitions of the same disk.

If the MySQL server is acting as a replica, you can set the system variable `replica_load_tmpdir` to specify a separate directory for holding temporary files when replicating `LOAD DATA` statements. This directory should be in a disk-based file system (not a memory-based file system) so that the temporary files used to replicate `LOAD DATA` can survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process. However, replication can now continue after a restart if the temporary files have been removed.

MySQL arranges that temporary files are removed if `mysqld` is terminated. On platforms that support it (such as Unix), this is done by unlinking the file after opening it. The disadvantage of this is that the name does not appear in directory listings and you do not see a big temporary file that fills up the file system in which the temporary file directory is located. (In such cases, `ls -lFl` may be helpful in identifying large files associated with `mysqld`.)
When sorting (ORDER BY or GROUP BY), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

\[
\text{length of what is sorted} + \text{sizeof(row pointer)} \times \text{number of matched rows} \times 2
\]

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some statements, MySQL creates temporary SQL tables that are not hidden and have names that begin with `#sql`.

Some SELECT queries creates temporary SQL tables to hold intermediate results.

DDL operations that rebuild the table and are not performed online using the ALGORITHM=INPLACE technique create a temporary copy of the original table in the same directory as the original table.

Online DDL operations may use temporary log files for recording concurrent DML, temporary sort files when creating an index, and temporary intermediate tables files when rebuilding the table. For more information, see Section 17.12.3, “Online DDL Space Requirements”.

InnoDB user-created temporary tables and on-disk internal temporary tables are created in a temporary tablespace file named `ibtmp1` in the MySQL data directory. For more information, see Section 17.6.3.5, “Temporary Tablespaces”.

See also Section 17.15.7, “InnoDB INFORMATION_SCHEMA Temporary Table Info Table”.

The optional EXTENDED modifier causes SHOW TABLES to list hidden tables created by failed ALTER TABLE statements. See Section 15.7.7.38, “SHOW TABLES Statement”.

### B.3.3.6 How to Protect or Change the MySQL Unix Socket File

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On some versions of Unix, anyone can delete files in the `/tmp` directory or other similar directories used for temporary files. If the socket file is located in such a directory on your system, this might cause problems.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (root). To do this, set the sticky bit on the `/tmp` directory by logging in as root and using the following command:

```
$> chmod +t /tmp
```

You can check whether the sticky bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in `/etc/my.cnf`:

  ```
  [mysql]
  socket=~path/to/socket
  [client]
  ```
Query-Related Issues

socket=/path/to/socket

See Section 6.2.2.2, “Using Option Files”.

• Specify a --socket option on the command line to mysqld_safe and when you run client programs.
• Set the MYSQL_UNIX_PORT environment variable to the path of the Unix socket file.
• Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the MYSQL_UNIX_ADDR option when you run CMake. See Section 2.8.7, “MySQL Source-Configuration Options”.

You can test whether the new socket location works by attempting to connect to the server with this command:

$> mysqladmin --socket=/path/to/socket version

B.3.3.7 Time Zone Problems

If you have a problem with SELECT NOW() returning values in UTC and not your local time, you have to tell the server your current time zone. The same applies if UNIX_TIMESTAMP() returns the wrong value. This should be done for the environment in which the server runs (for example, in mysqld_safe or mysql.server). See Section 6.9, “Environment Variables”.

You can set the time zone for the server with the --timezone.timezone_name option to mysqld_safe. You can also set it by setting the TZ environment variable before you start mysqld.

The permissible values for --timezone or TZ are system dependent. Consult your operating system documentation to see what values are acceptable.

B.3.4 Query-Related Issues

B.3.4.1 Case Sensitivity in String Searches

For nonbinary strings (CHAR, VARCHAR, TEXT), string searches use the collation of the comparison operands. For binary strings (BINARY, VARBINARY, BLOB), comparisons use the numeric values of the bytes in the operands; this means that for alphabetic characters, comparisons are case-sensitive.

A comparison between a nonbinary string and binary string is treated as a comparison of binary strings.

Simple comparison operations (>=, >, =, <, <=, sorting, and grouping) are based on each character's “sort value.” Characters with the same sort value are treated as the same character. For example, if e and é have the same sort value in a given collation, they compare as equal.

The default character set and collation are utf8mb4 and utf8mb4_0900_ai_ci, so nonbinary string comparisons are case-insensitive by default. This means that if you search with col_name LIKE 'a%', you get all column values that start with A or a. To make this search case-sensitive, make sure that one of the operands has a case-sensitive or binary collation. For example, if you are comparing a column and a string that both have the utf8mb4 character set, you can use the COLLATE operator to cause either operand to have the utf8mb4_0900_as_cs or utf8mb4_bin collation:

```
col_name COLLATE utf8mb4_0900_as_cs LIKE 'a%'
col_name LIKE 'a%' COLLATE utf8mb4_0900_as_cs
col_name COLLATE utf8mb4_bin LIKE 'a%'
col_name LIKE 'a%' COLLATE utf8mb4_bin
```

If you want a column always to be treated in case-sensitive fashion, declare it with a case-sensitive or binary collation. See Section 15.1.20, “CREATE TABLE Statement”.

5444
To cause a case-sensitive comparison of nonbinary strings to be case-insensitive, use `COLLATE` to name a case-insensitive collation. The strings in the following example normally are case-sensitive, but `COLLATE` changes the comparison to be case-insensitive:

```sql
mysql> SET NAMES 'utf8mb4';
mysql> SET @s1 = 'MySQL' COLLATE utf8mb4_bin,
    @s2 = 'mysql' COLLATE utf8mb4_bin;
mysql> SELECT @s1 = @s2;
+-----------+
<table>
<thead>
<tr>
<th>@s1 = @s2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+-----------+
mysql> SELECT @s1 COLLATE utf8mb4_0900_ai_ci = @s2;
+--------------------------------------+
<table>
<thead>
<tr>
<th>@s1 COLLATE utf8mb4_0900_ai_ci = @s2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+--------------------------------------+
```

A binary string is case-sensitive in comparisons. To compare the string as case-insensitive, convert it to a nonbinary string and use `COLLATE` to name a case-insensitive collation:

```sql
mysql> SET @s = BINARY 'MySQL';
mysql> SELECT @s = 'mysql';
+--------------+
<table>
<thead>
<tr>
<th>@s = 'mysql'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+--------------+
mysql> SELECT CONVERT(@s USING utf8mb4) COLLATE utf8mb4_0900_ai_ci = 'mysql';
+----------------------------------------------------------------+
<table>
<thead>
<tr>
<th>CONVERT(@s USING utf8mb4) COLLATE utf8mb4_0900_ai_ci = 'mysql'</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+----------------------------------------------------------------+
```

To determine whether a value is compared as a nonbinary or binary string, use the `COLLATION()` function. This example shows that `VERSION()` returns a string that has a case-insensitive collation, so comparisons are case-insensitive:

```sql
mysql> SELECT COLLATION(VERSION());
+----------------------+
<table>
<thead>
<tr>
<th>COLLATION(VERSION())</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8mb3_general_ci</td>
</tr>
</tbody>
</table>
+----------------------+
```

For binary strings, the collation value is `binary`, so comparisons are case sensitive. One context in which you can expect to see `binary` is for compression functions, which return binary strings as a general rule:

```sql
mysql> SELECT COLLATION(COMPRESS('x'));
+--------------------------+
<table>
<thead>
<tr>
<th>COLLATION(COMPRESS('x'))</th>
</tr>
</thead>
<tbody>
<tr>
<td>binary</td>
</tr>
</tbody>
</table>
+--------------------------+
```

To check the sort value of a string, the `WEIGHT_STRING()` may be helpful. See Section 14.8, “String Functions and Operators”.

**B.3.4.2 Problems Using DATE Columns**
The format of a DATE value is 'YYYY-MM-DD'. According to standard SQL, no other format is permitted. You should use this format in UPDATE expressions and in the WHERE clause of SELECT statements. For example:

```
SELECT * FROM t1 WHERE date >= '2003-05-05';
```

As a convenience, MySQL automatically converts a date to a number if the date is used in numeric context and vice versa. MySQL also permits a "relaxed" string format when updating and in a WHERE clause that compares a date to a DATE, DATETIME, or TIMESTAMP column. "Relaxed" format means that any punctuation character may be used as the separator between parts. For example, '2004-08-15' and '2004#08#15' are equivalent. MySQL can also convert a string containing no separators (such as '20040815'), provided it makes sense as a date.

When you compare a DATE, TIME, DATETIME, or TIMESTAMP to a constant string with the <, <=, =, >=, >, or BETWEEN operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more "relaxed" string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns
- When you compare a DATE, TIME, DATETIME, or TIMESTAMP column to an expression
- When you use any comparison method other than those just listed, such as IN or STRCMP().

For those exceptions, the comparison is done by converting the objects to strings and performing a string comparison.

To be on the safe side, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special "zero" date '0000-00-00' can be stored and retrieved as '0000-00-00'. When a '0000-00-00' date is used through Connector/ODBC, it is automatically converted to NULL because ODBC cannot handle that kind of date.

Because MySQL performs the conversions just described, the following statements work (assume that idate is a DATE column):

```
INSERT INTO t1 (idate) VALUES (19970505);
INSERT INTO t1 (idate) VALUES ('19970505');
INSERT INTO t1 (idate) VALUES ('97-05-05');
INSERT INTO t1 (idate) VALUES ('1997.05.05');
INSERT INTO t1 (idate) VALUES ('1997 05 05');
INSERT INTO t1 (idate) VALUES ('0000-00-00');
SELECT idate FROM t1 WHERE idate >= '1997-05-05';
SELECT idate FROM t1 WHERE idate >= 19970505;
SELECT MOD(idate,100) FROM t1 WHERE idate >= 19970505;
SELECT idate FROM t1 WHERE idate >= '19970505';
```

However, the following statement does not work:

```
SELECT idate FROM t1 WHERE STRCMP(idate,'20030505')=0;
```

STRCMP() is a string function, so it converts idate to a string in 'YYYY-MM-DD' format and performs a string comparison. It does not convert '20030505' to the date '2003-05-05' and perform a date comparison.

If you enable the ALLOW_INVALID_DATES SQL mode, MySQL permits you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12. This makes MySQL very convenient for Web applications where you obtain year,
month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

MySQL permits you to store dates where the day or month and day are zero. This is convenient if you want to store a birthdate in a \texttt{DATE} column and you know only part of the date. To disallow zero month or day parts in dates, enable the \texttt{NO\_ZERO\_IN\_DATE} mode.

MySQL permits you to store a "zero" value of \texttt{'0000-00-00'} as a "dummy date." This is in some cases more convenient than using \texttt{NULL} values. If a date to be stored in a \texttt{DATE} column cannot be converted to any reasonable value, MySQL stores \texttt{'0000-00-00'}. To disallow \texttt{'0000-00-00'}, enable the \texttt{NO\_ZERO\_DATE} mode.

To have MySQL check all dates and accept only legal dates (unless overridden by \texttt{IGNORE}), set the \texttt{sql\_mode} system variable to \texttt{"NO\_ZERO\_IN\_DATE,NO\_ZERO\_DATE"}.

\subsection*{B.3.4.3 Problems with NULL Values}

The concept of the \texttt{NULL} value is a common source of confusion for newcomers to SQL, who often think that \texttt{NULL} is the same thing as an empty string \texttt{''}. This is not the case. For example, the following statements are completely different:

\begin{verbatim}
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
\end{verbatim}

Both statements insert a value into the \texttt{phone} column, but the first inserts a \texttt{NULL} value and the second inserts an empty string. The meaning of the first can be regarded as "phone number is not known" and the meaning of the second can be regarded as "the person is known to have no phone, and thus no phone number."

To help with \texttt{NULL} handling, you can use the \texttt{IS NULL} and \texttt{IS NOT NULL} operators and the \texttt{IFNULL()} function.

In SQL, the \texttt{NULL} value is never true in comparison to any other value, even \texttt{NULL}. An expression that contains \texttt{NULL} always produces a \texttt{NULL} value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return \texttt{NULL}:

\begin{verbatim}
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
\end{verbatim}

To search for column values that are \texttt{NULL}, you cannot use an \texttt{expr = NULL} test. The following statement returns no rows, because \texttt{expr = NULL} is never true for any expression:

\begin{verbatim}
mysql> SELECT * FROM my_table WHERE phone = NULL;
\end{verbatim}

To look for \texttt{NULL} values, you must use the \texttt{IS NULL} test. The following statements show how to find the \texttt{NULL} phone number and the empty phone number:

\begin{verbatim}
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
\end{verbatim}

See Section 5.3.4.6, “Working with NULL Values”, for additional information and examples.

You can add an index on a column that can have \texttt{NULL} values if you are using the \texttt{MyISAM}, \texttt{InnoDB}, or \texttt{MEMORY} storage engine. Otherwise, you must declare an indexed column \texttt{NOT NULL}, and you cannot insert \texttt{NULL} into the column.

When reading data with \texttt{LOAD DATA}, empty or missing columns are updated with \texttt{''}. To load a \texttt{NULL} value into a column, use \texttt{\textbackslash N} in the data file. The literal word \texttt{NULL} may also be used under some circumstances. See Section 15.2.9, “LOAD DATA Statement".

5447
When using `DISTINCT`, `GROUP BY`, or `ORDER BY`, all `NULL` values are regarded as equal.

When using `ORDER BY`, `NULL` values are presented first, or last if you specify `DESC` to sort in descending order.

Aggregate (group) functions such as `COUNT()`, `MIN()`, and `SUM()` ignore `NULL` values. The exception to this is `COUNT(*)`, which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-`NULL` values in the `age` column:

```sql
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles `NULL` values in special ways. For example, if you insert `NULL` into an integer or floating-point column that has the `AUTO_INCREMENT` attribute, the next number in the sequence is inserted. Under certain conditions, if you insert `NULL` into a `TIMESTAMP` column, the current date and time is inserted; this behavior depends in part on the server SQL mode (see Section 7.1.11, “Server SQL Modes”) as well as the value of the `explicit_defaults_for_timestamp` system variable.

### B.3.4.4 Problems with Column Aliases

An alias can be used in a query select list to give a column a different name. You can use the alias in `GROUP BY`, `ORDER BY`, or `HAVING` clauses to refer to the column:

```sql
SELECT SQRT(a*b) AS root FROM tbl_name GROUP BY root HAVING root > 0;
SELECT id, COUNT(*) AS cnt FROM tbl_name GROUP BY id HAVING cnt > 0;
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL disallows references to column aliases in a `WHERE` clause. This restriction is imposed because when the `WHERE` clause is evaluated, the column value may not yet have been determined. For example, the following query is illegal:

```sql
SELECT id, COUNT(*) AS cnt FROM tbl_name WHERE cnt > 0 GROUP BY id;
```

The `WHERE` clause determines which rows should be included in the `GROUP BY` clause, but it refers to the alias of a column value that is not known until after the rows have been selected, and grouped by the `GROUP BY`.

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```sql
SELECT 1 AS 'one', 2 AS 'two';
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal. For example, this statement groups by the values in column `id`, referenced using the alias `a`:

```sql
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name GROUP BY 'a';
```

This statement groups by the literal string `a` and does not work as you may expect:

```sql
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name GROUP BY 'a';
```

### B.3.4.5 Rollback Failure for Nontransactional Tables
If you receive the following message when trying to perform a ROLLBACK, it means that one or more of the tables you used in the transaction do not support transactions:

Warning: Some non-transactional changed tables couldn't be rolled back

These nontransactional tables are not affected by the ROLLBACK statement.

If you were not deliberately mixing transactional and nontransactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your mysqld server (or that was disabled with a startup option). If mysqld does not support a storage engine, it instead creates the table as a MyISAM table, which is nontransactional.

You can check the storage engine for a table by using either of these statements:

```
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See Section 15.7.7.37, “SHOW TABLE STATUS Statement”, and Section 15.7.7.11, “SHOW CREATE TABLE Statement”.

To check which storage engines your mysqld server supports, use this statement:

```
SHOW ENGINES;
```

See Section 15.7.7.17, “SHOW ENGINES Statement” for full details.

### B.3.4.6 Deleting Rows from Related Tables

If the total length of the DELETE statement for related_table is more than the default value of the max_allowed_packet system variable, you should split it into smaller parts and execute multiple DELETE statements. You probably get the fastest DELETE by specifying only 100 to 1,000 related_column values per statement if the related_column is indexed. If the related_column isn't indexed, the speed is independent of the number of arguments in the IN clause.

### B.3.4.7 Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that returns no rows, you should use the following procedure to find out what is wrong:

1. Test the query with EXPLAIN to check whether you can find something that is obviously wrong. See Section 15.8.2, “EXPLAIN Statement”.
2. Select only those columns that are used in the WHERE clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it is a good idea to use LIMIT 10 with the query.
4. Issue a SELECT for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing FLOAT or DOUBLE columns with numbers that have decimals, you cannot use equality (=) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the FLOAT to a DOUBLE fixes this. See Section B.3.4.8, “Problems with Floating-Point Values”.
6. If you still cannot figure out what is wrong, create a minimal test that can be run with mysql test < query.sql that shows your problems. You can create a test file by dumping the tables with mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql. Open the file in
an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your `SELECT` statement at the end of the file.

Verify that the test file demonstrates the problem by executing these commands:

```
$> mysqladmin create test2
$> mysql test2 < query.sql
```

Attach the test file to a bug report, which you can file using the instructions in Section 1.6, “How to Report Bugs or Problems”.

**B.3.4.8 Problems with Floating-Point Values**

Floating-point numbers sometimes cause confusion because they are approximate and not stored as exact values. A floating-point value as written in an SQL statement may not be the same as the value represented internally. Attempts to treat floating-point values as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. The `FLOAT` and `DOUBLE` data types are subject to these issues. For `DECIMAL` columns, MySQL performs operations with a precision of 65 decimal digits, which should solve most common inaccuracy problems.

The following example uses `DOUBLE` to demonstrate how calculations that are done using floating-point operations are subject to floating-point error.

```sql
mysql> CREATE TABLE t1 (i INT, d1 DOUBLE, d2 DOUBLE);
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
-> (2, -13.20, 0.00), (2, 0.00, 0.00), (2, 59.60, 46.40),
-> (2, 30.40, 30.40), (3, 37.00, 7.40), (3, -29.60, 0.00),
-> (4, 0.00, 0.00), (4, -10.60, 0.00), (4, -34.00, 0.00),
-> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
-> (6, 0.00, 0.00), (6, -51.40, 0.00);
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
-> FROM t1 GROUP BY i HAVING a <> b;
```

+-----+---+---+
<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>21.4</td>
<td>21.4</td>
</tr>
<tr>
<td>2</td>
<td>76.8</td>
<td>76.8</td>
</tr>
<tr>
<td>3</td>
<td>7.4</td>
<td>7.4</td>
</tr>
<tr>
<td>4</td>
<td>15.4</td>
<td>15.4</td>
</tr>
<tr>
<td>5</td>
<td>7.2</td>
<td>7.2</td>
</tr>
<tr>
<td>6</td>
<td>-51.4</td>
<td>0</td>
</tr>
</tbody>
</table>
+-----+---+---+

The result is correct. Although the first five records look like they should not satisfy the comparison (the values of `a` and `b` do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on factors such as computer architecture or the compiler version or optimization level. For example, different CPUs may evaluate floating-point numbers differently.

If columns `d1` and `d2` had been defined as `DECIMAL` rather than `DOUBLE`, the result of the `SELECT` query would have contained only one row—the last one shown above.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
```

```
  ```
Conversely, to get rows where the numbers are the same, the test should find differences within the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
   -> GROUP BY i HAVING ABS(a - b) <= 0.0001;
```

<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>21.4</td>
<td>21.4</td>
</tr>
<tr>
<td>2</td>
<td>76.8</td>
<td>76.8</td>
</tr>
<tr>
<td>3</td>
<td>7.4</td>
<td>7.4</td>
</tr>
<tr>
<td>4</td>
<td>15.4</td>
<td>15.4</td>
</tr>
<tr>
<td>5</td>
<td>7.2</td>
<td>7.2</td>
</tr>
</tbody>
</table>

5 rows in set (0.03 sec)

Floating-point values are subject to platform or implementation dependencies. Suppose that you execute the following statements:

```sql
CREATE TABLE t1(c1 FLOAT(53,0), c2 FLOAT(53,0));
INSERT INTO t1 VALUES('1e+52','-1e+52');
SELECT * FROM t1;
```

On some platforms, the `SELECT` statement returns `inf` and `-inf`. On others, it returns `0` and `-0`.

An implication of the preceding issues is that if you attempt to create a replica by dumping table contents with `mysqldump` on the source and reloading the dump file into the replica, tables containing floating-point columns might differ between the two hosts.

**B.3.5 Optimizer-Related Issues**

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL does not have enough information about the data at hand and has to make “educated” guesses about the data.

For the cases when MySQL does not do the "right" thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:

  ```sql
  mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
  ```

  `EXPLAIN` is discussed in more detail in Section 15.8.2, “EXPLAIN Statement”.

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See Section 15.7.3.1, “ANALYZE TABLE Statement”.

- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

  ```sql
  SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
  WHERE t1.col_name=t2.col_name;
  ```

  `USE INDEX` and `IGNORE INDEX` may also be useful. See Section 10.9.4, “Index Hints”.
Table Definition-Related Issues

- Global and table-level STRAIGHT_JOIN. See Section 15.2.13, “SELECT Statement”.

- You can tune global or thread-specific system variables. For example, start mysqld with the \texttt{--max-seeks-for-key=1000} option or use \texttt{SET max_seeks_for_key=1000} to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 7.1.8, “Server System Variables”.

B.3.6 Table Definition-Related Issues

B.3.6.1 Problems with ALTER TABLE

If you get a duplicate-key error when using ALTER TABLE to change the character set or collation of a character column, the cause is either that the new column collation maps two keys to the same value or that the table is corrupted. In the latter case, you should run REPAIR TABLE on the table. REPAIR TABLE works for MyISAM, ARCHIVE, and CSV tables.

If you use ALTER TABLE on a transactional table or if you are using Windows, ALTER TABLE unlocks the table if you had done a LOCK TABLE on it. This is done because InnoDB and these operating systems cannot drop a table that is in use.

B.3.6.2 TEMPORARY Table Problems

Temporary tables created with CREATE TEMPORARY TABLE have the following limitations:

- TEMPORARY tables are supported only by the InnoDB, MEMORY, MyISAM, and MERGE storage engines.

- Temporary tables are not supported for NDB Cluster.

- The \texttt{SHOW TABLES} statement does not list TEMPORARY tables.

- To rename TEMPORARY tables, RENAME TABLE does not work. Use ALTER TABLE instead:

  \begin{verbatim}
  ALTER TABLE old_name RENAME new_name;
  \end{verbatim}

- You cannot refer to a TEMPORARY table more than once in the same query. For example, the following does not work:

  \begin{verbatim}
  SELECT * FROM temp_table JOIN temp_table AS t2;
  \end{verbatim}

  The statement produces this error:

  \begin{verbatim}
  ERROR 1137: Can't reopen table: 'temp_table'
  \end{verbatim}

  You can work around this issue if your query permits use of a common table expression (CTE) rather than a TEMPORARY table. For example, this fails with the Can't reopen table error:

  \begin{verbatim}
  CREATE TEMPORARY TABLE t SELECT 1 AS col_a, 2 AS col_b;
  SELECT * FROM t AS t1 JOIN t AS t2;
  \end{verbatim}

  To avoid the error, use a \texttt{WITH} clause that defines a CTE, rather than the TEMPORARY table:

  \begin{verbatim}
  WITH cte AS (SELECT 1 AS col_a, 2 AS col_b)
  SELECT * FROM cte AS t1 JOIN cte AS t2;
  \end{verbatim}

- The Can't reopen table error also occurs if you refer to a temporary table multiple times in a stored function under different aliases, even if the references occur in different statements within the function. It may occur for temporary tables created outside stored functions and referred to across multiple calling and callee functions.
• If a TEMPORARY is created with the same name as an existing non-TEMPORARY table, the non-TEMPORARY table is hidden until the TEMPORARY table is dropped, even if the tables use different storage engines.

• There are known issues in using temporary tables with replication. See Section 19.5.1.31, “Replication and Temporary Tables”, for more information.

B.3.7 Known Issues in MySQL

This section lists known issues in recent versions of MySQL.

For information about platform-specific issues, see the installation and debugging instructions in Section 2.1, “General Installation Guidance”, and Section 7.9, “Debugging MySQL”.

The following problems are known:

• Subquery optimization for IN is not as effective as for =.

• Even if you use lower_case_table_names=2 (which enables MySQL to remember the case used for databases and table names), MySQL does not remember the case used for database names for the function DATABASE() or within the various logs (on case-insensitive systems).

• Dropping a FOREIGN KEY constraint does not work in replication because the constraint may have another name on the replica.

• REPLACE (and LOAD DATA with the REPLACE option) does not trigger ON DELETE CASCADE.

• DISTINCT with ORDER BY does not work inside GROUP_CONCAT() if you do not use all and only those columns that are in the DISTINCT list.

• When inserting a big integer value (between $2^{63}$ and $2^{64}-1$) into a decimal or string column, it is inserted as a negative value because the number is evaluated in signed integer context.

• With statement-based binary logging, the source server writes the executed queries to the binary log. This is a very fast, compact, and efficient logging method that works perfectly in most cases. However, it is possible for the data on the source and replica to become different if a query is designed in such a way that the data modification is nondeterministic (generally not a recommended practice, even outside of replication).

For example:

• CREATE TABLE ... SELECT or INSERT ... SELECT statements that insert zero or NULL values into an AUTO_INCREMENT column.

• DELETE if you are deleting rows from a table that has foreign keys with ON DELETE CASCADE properties.

• REPLACE ... SELECT, INSERT IGNORE ... SELECT if you have duplicate key values in the inserted data.

If and only if the preceding queries have no ORDER BY clause guaranteeing a deterministic order.

For example, for INSERT ... SELECT with no ORDER BY, the SELECT may return rows in a different order (which results in a row having different ranks, hence getting a different number in the AUTO_INCREMENT column), depending on the choices made by the optimizers on the source and replica.

A query is optimized differently on the source and replica only if:
• The table is stored using a different storage engine on the source than on the replica. (It is possible
to use different storage engines on the source and replica. For example, you can use InnoDB on the
source, but MyISAM on the replica if the replica has less available disk space.)

• MySQL buffer sizes (key_buffer_size, and so on) are different on the source and replica.

• The source and replica run different MySQL versions, and the optimizer code differs between these
versions.

This problem may also affect database restoration using `mysqlbinlog`|`mysql`.

The easiest way to avoid this problem is to add an ORDER BY clause to the aforementioned
nondeterministic queries to ensure that the rows are always stored or modified in the same order. Using
row-based or mixed logging format also avoids the problem.

• Log file names are based on the server host name if you do not specify a file name with the startup
option. To retain the same log file names if you change your host name to something else, you
must explicitly use options such as --log-bin=old_host_name-bin. See Section 7.1.7, “Server
Command Options”. Alternatively, rename the old files to reflect your host name change. If these are
binary logs, you must edit the binary log index file and fix the binary log file names there as well. (The
same is true for the relay logs on a replica.)

• `mysqlbinlog` does not delete temporary files left after a LOAD DATA statement. See Section 6.6.9,
“mysqlbinlog — Utility for Processing Binary Log Files”.

• RENAME does not work with TEMPORARY tables or tables used in a MERGE table.

• When using SET CHARACTER SET, you cannot use translated characters in database, table, and
column names.

• The server uses only the first max_sort_length bytes when comparing data values. This means
that values cannot reliably be used in GROUP BY, ORDER BY, or DISTINCT if they differ only after the
first max_sort_length bytes. To work around this, increase the variable value. The default value of
max_sort_length is 1024 and can be changed at server startup time or at runtime.

• Numeric calculations are done with BIGINT or DOUBLE (both are normally 64 bits long). Which precision
you get depends on the function. The general rule is that bit functions are performed with BIGINT
precision, IF() and ELT() with BIGINT or DOUBLE precision, and the rest with DOUBLE precision.
You should try to avoid using unsigned long long values if they resolve to be larger than 63 bits
(9223372036854775807) for anything other than bit fields.

• You can have up to 255 ENUM and SET columns in one table.

• In MIN(), MAX(), and other aggregate functions, MySQL currently compares ENUM and SET columns by
their string value rather than by the string's relative position in the set.

• In an UPDATE statement, columns are updated from left to right. If you refer to an updated column, you
get the updated value instead of the original value. For example, the following statement increments KEY
by 2, not 1:

  mysql> UPDATE tbl_name SET KEY=KEY+1,KEY=KEY+1;

• You can refer to multiple temporary tables in the same query, but you cannot refer to any given
temporary table more than once. For example, the following does not work:

  mysql> SELECT * FROM temp_table, temp_table AS t2;
  ERROR 1137: Can't reopen table: 'temp_table'
• The optimizer may handle \texttt{DISTINCT} differently when you are using “hidden” columns in a join than when you are not. In a join, hidden columns are counted as part of the result (even if they are not shown), whereas in normal queries, hidden columns do not participate in the \texttt{DISTINCT} comparison.

An example of this is:

\begin{verbatim}
SELECT DISTINCT mp3id FROM band_downloads
WHERE userid = 9 ORDER BY id DESC;
\end{verbatim}

and

\begin{verbatim}
SELECT DISTINCT band_downloads.mp3id
FROM band_downloads,band_mp3
WHERE band_downloads.userid = 9
AND band_mp3.id = band_downloads.mp3id
ORDER BY band_downloads.id DESC;
\end{verbatim}

In the second case, you may get two identical rows in the result set (because the values in the hidden \texttt{id} column may differ).

Note that this happens only for queries that do not have the \texttt{ORDER BY} columns in the result.

• If you execute a \texttt{PROCEDURE} on a query that returns an empty set, in some cases the \texttt{PROCEDURE} does not transform the columns.

• Creation of a table of type \texttt{MERGE} does not check whether the underlying tables are compatible types.

• If you use \texttt{ALTER TABLE} to add a \texttt{UNIQUE} index to a table used in a \texttt{MERGE} table and then add a normal index on the \texttt{MERGE} table, the key order is different for the tables if there was an old, non-\texttt{UNIQUE} key in the table. This is because \texttt{ALTER TABLE} puts \texttt{UNIQUE} indexes before normal indexes to be able to detect duplicate keys as early as possible.

MySQL Glossary

These terms are commonly used in information about the MySQL database server.

A

.ARM file
   Metadata for ARCHIVE tables. Contrast with .ARZ file. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product. See Also .ARZ file, MySQL Enterprise Backup, mysqlbackup command.

.ARZ file
   Data for ARCHIVE tables. Contrast with .ARM file. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product. See Also .ARM file, MySQL Enterprise Backup, mysqlbackup command.

ACID
   An acronym standing for atomicity, consistency, isolation, and durability. These properties are all desirable in a database system, and are all closely tied to the notion of a transaction. The transactional features of InnoDB adhere to the ACID principles.

Transactions are atomic units of work that can be committed or rolled back. When a transaction makes multiple changes to the database, either all the changes succeed when the transaction is committed, or all the changes are undone when the transaction is rolled back.

The database remains in a consistent state at all times — after each commit or rollback, and while transactions are in progress. If related data is being updated across multiple tables, queries see either all old values or all new values, not a mix of old and new values.

Transactions are protected (isolated) from each other while they are in progress; they cannot interfere with each other or see each other's uncommitted data. This isolation is achieved through the locking mechanism. Experienced users can adjust the isolation level, trading off less protection in favor of increased performance and concurrency, when they can be sure that the transactions really do not interfere with each other.

The results of transactions are durable: once a commit operation succeeds, the changes made by that transaction are safe from power failures, system crashes, race conditions, or other potential dangers that many non-database applications are vulnerable to. Durability typically involves writing to disk storage, with a certain amount of redundancy to protect against power failures or software crashes during write operations. (In InnoDB, the doublewrite buffer assists with durability.)

See Also atomic, commit, concurrency, doublewrite buffer, isolation level, locking, rollback, transaction.

adaptive flushing
   An algorithm for InnoDB tables that smooths out the I/O overhead introduced by checkpoints. Instead of flushing all modified pages from the buffer pool to the data files at once, MySQL periodically flushes small sets of modified pages. The adaptive flushing algorithm extends this process by estimating the optimal rate to perform these periodic flushes, based on the rate of flushing and how fast redo information is generated.

See Also buffer pool, checkpoint, data files, flush, InnoDB, page, redo log.

adaptive hash index
   An optimization for InnoDB tables that can speed up lookups using = and IN operators, by constructing a hash index in memory. MySQL monitors index searches for InnoDB tables, and if queries could benefit from a hash index, it builds one automatically for index pages that are frequently accessed. In a sense, the adaptive hash index configures MySQL at runtime to take advantage of ample main memory, coming closer to the architecture of main-memory databases. This feature is controlled by the innodb_adaptive_hash_index configuration.
option. Because this feature benefits some workloads and not others, and the memory used for the hash index is reserved in the buffer pool, typically you should benchmark with this feature both enabled and disabled.

The hash index is always built based on an existing B-tree index on the table. MySQL can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches against the index. A hash index can be partial; the whole B-tree index does not need to be cached in the buffer pool.

See Also B-tree, buffer pool, hash index, page, secondary index.

ADO.NET

An object-relational mapping (ORM) framework for applications built using .NET technologies such as ASP.NET. Such applications can interface with MySQL through the Connector/NET component.

See Also .NET, ASP.net, Connector/NET, Mono, Visual Studio.

AIO

Acronym for asynchronous I/O. You might see this acronym in InnoDB messages or keywords.

See Also asynchronous I/O.

ANSI

In ODBC, an alternative method of supporting character sets and other internationalization aspects. Contrast with Unicode. Connector/ODBC 3.51 is an ANSI driver, while Connector/ODBC 5.1 is a Unicode driver.

See Also Connector/ODBC, ODBC, Unicode.

API

APIs provide low-level access to the MySQL protocol and MySQL resources from client programs. Contrast with the higher-level access provided by a Connector.

See Also C API, client, connector, native C API, Perl API, PHP API, Python API, Ruby API.

application programming interface (API)

A set of functions or procedures. An API provides a stable set of names and types for functions, procedures, parameters, and return values.

apply

When a backup produced by the MySQL Enterprise Backup product does not include the most recent changes that occurred while the backup was underway, the process of updating the backup files to include those changes is known as the apply step. It is specified by the apply-log option of the mysqlbackup command.

Before the changes are applied, we refer to the files as a raw backup. After the changes are applied, we refer to the files as a prepared backup. The changes are recorded in the ibbackup_logfile file; once the apply step is finished, this file is no longer necessary.

See Also hot backup, ibbackup_logfile, MySQL Enterprise Backup, prepared backup, raw backup.

AS

A Kerberos authentication server. AS can also refer to the authentication service provided by an authentication server.

See Also authentication server.

ASP.net

A framework for developing web-based applications using .NET technologies and languages. Such applications can interface with MySQL through the Connector/NET component.

Another technology for writing server-side web pages with MySQL is PHP.

See Also .NET, ADO.NET, Connector/NET, Mono, PHP, Visual Studio.

assembly

A library of compiled code in a .NET system, accessed through Connector/NET. Stored in the GAC to allow versioning without naming conflicts.
asynchronous I/O
A type of I/O operation that allows other processing to proceed before the I/O is completed. Also known as nonblocking I/O and abbreviated as AIO. InnoDB uses this type of I/O for certain operations that can run in parallel without affecting the reliability of the database, such as reading pages into the buffer pool that have not actually been requested, but might be needed soon.

Historically, InnoDB used asynchronous I/O on Windows systems only. Starting with the InnoDB Plugin 1.1 and MySQL 5.5, InnoDB uses asynchronous I/O on Linux systems. This change introduces a dependency on libaio. Asynchronous I/O on Linux systems is configured using the innodb_use_native_aio option, which is enabled by default. On other Unix-like systems, InnoDB uses synchronous I/O only.

atomic
In the SQL context, transactions are units of work that either succeed entirely (when committed) or have no effect at all (when rolled back). The indivisible (“atomic”) property of transactions is the “A” in the acronym ACID. See Also ACID, commit, rollback, transaction.

atomic DDL
An atomic DDL statement is one that combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic transaction. The transaction is either fully committed or rolled back, even if the server halts during the operation. Atomic DDL support was added in MySQL 8.0. For more information, see Section 15.1.1, “Atomic Data Definition Statement Support”.
See Also binary log, data dictionary, DDL, storage engine.

atomic instruction
Special instructions provided by the CPU, to ensure that critical low-level operations cannot be interrupted.

authentication server
In Kerberos, a service that provides the initial ticket needed to obtain a ticket-granting ticket (TGT) that is needed to obtain other tickets from the ticket-granting server (TGS). The authentication server (AS) combined with a TGS make up a key distribution center (KDC).
See Also key distribution center, ticket-granting server.

auto-increment
A property of a table column (specified by the AUTO_INCREMENT keyword) that automatically adds an ascending sequence of values in the column.

It saves work for the developer, not to have to produce new unique values when inserting new rows. It provides useful information for the query optimizer, because the column is known to be not null and with unique values. The values from such a column can be used as lookup keys in various contexts, and because they are auto-generated there is no reason to ever change them; for this reason, primary key columns are often specified as auto-incrementing.

Auto-increment columns can be problematic with statement-based replication, because replaying the statements on a replica might not produce the same set of column values as on the source, due to timing issues. When you have an auto-incrementing primary key, you can use statement-based replication only with the setting innodb_autoinc_lock_mode=1. If you have innodb_autoinc_lock_mode=2, which allows higher concurrency for insert operations, use row-based replication rather than statement-based replication. The setting innodb_autoinc_lock_mode=0 should not be used except for compatibility purposes.

Consecutive lock mode (innodb_autoinc_lock_mode=1) is the default setting prior to MySQL 8.0.3. As of MySQL 8.0.3, interleaved lock mode (innodb_autoinc_lock_mode=2) is the default, which reflects the change from statement-based to row-based replication as the default replication type.
See Also auto-increment locking, innodb_autoinc_lock_mode, primary key, row-based replication, statement-based replication.

auto-increment locking
The convenience of an auto-increment primary key involves some tradeoff with concurrency. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values. InnoDB includes optimizations and the innodb_autoinc_lock_mode option so that you can configure and optimal balance between predictable sequences of auto-increment values and maximum concurrency for insert operations.

See Also auto-increment, concurrency, innodb_autoinc_lock_mode.

autocommit
A setting that causes a commit operation after each SQL statement. This mode is not recommended for working with InnoDB tables with transactions that span several statements. It can help performance for read-only transactions on InnoDB tables, where it minimizes overhead from locking and generation of undo data, especially in MySQL 5.6.4 and up. It is also appropriate for working with MyISAM tables, where transactions are not applicable.

See Also commit, locking, read-only transaction, SQL, transaction, undo.

availability
The ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Often paired with scalability as critical aspects of a large-scale deployment.

See Also scalability.

B

B-tree
A tree data structure that is popular for use in database indexes. The structure is kept sorted at all times, enabling fast lookup for exact matches (equals operator) and ranges (for example, greater than, less than, and BETWEEN operators). This type of index is available for most storage engines, such as InnoDB and MyISAM.

Because B-tree nodes can have many children, a B-tree is not the same as a binary tree, which is limited to 2 children per node.

Contrast with hash index, which is only available in the MEMORY storage engine. The MEMORY storage engine can also use B-tree indexes, and you should choose B-tree indexes for MEMORY tables if some queries use range operators.

The use of the term B-tree is intended as a reference to the general class of index design. B-tree structures used by MySQL storage engines may be regarded as variants due to sophistications not present in a classic B-tree design. For related information, refer to the InnoDB Page Structure Fil Header section of the MySQL Internals Manual.

See Also hash index.

backticks
Identifiers within MySQL SQL statements must be quoted using the backtick character (``) if they contain special characters or reserved words. For example, to refer to a table named FOOD or a column named SELECT, you would specify the identifiers as `FOOD` and `SELECT`. Since the backticks provide an extra level of safety, they are used extensively in program-generated SQL statements, where the identifier names might not be known in advance.

Many other database systems use double quotation marks (""") around such special names. For portability, you can enable ANSI_QUOTES mode in MySQL and use double quotation marks instead of backticks to qualify identifier names.
See Also SQL.

backup
The process of copying some or all table data and metadata from a MySQL instance, for safekeeping. Can also refer to the set of copied files. This is a crucial task for DBAs. The reverse of this process is the **restore** operation.

With MySQL, **physical backups** are performed by the MySQL Enterprise Backup product, and **logical backups** are performed by the `mysqldump` command. These techniques have different characteristics in terms of size and representation of the backup data, and speed (especially speed of the restore operation).

Backups are further classified as **hot**, **warm**, or **cold** depending on how much they interfere with normal database operation. (Hot backups have the least interference, cold backups the most.)
See Also cold backup, hot backup, logical backup, MySQL Enterprise Backup, mysqldump, physical backup, warm backup.

base column
A non-generated table column upon which a stored generated column or virtual generated column is based. In other words, a base column is a non-generated table column that is part of a generated column definition.
See Also generated column, stored generated column, virtual generated column.

beta
An early stage in the life of a software product, when it is available only for evaluation, typically without a definite release number or a number less than 1. InnoDB does not use the beta designation, preferring an **early adopter** phase that can extend over several point releases, leading to a **GA** release.
See Also early adopter, GA.

binary log
A file containing a record of all statements or row changes that attempt to change table data. The contents of the binary log can be replayed to bring replicas up to date in a **replication** scenario, or to bring a database up to date after restoring table data from a backup. The binary logging feature can be turned on and off, although Oracle recommends always enabling it if you use replication or perform backups.

You can examine the contents of the binary log, or replay it during replication or recovery, by using the `mysqlbinlog` command. For full information about the binary log, see Section 7.4.4, "The Binary Log". For MySQL configuration options related to the binary log, see Section 19.1.6.4, "Binary Logging Options and Variables".

For the MySQL Enterprise Backup product, the file name of the binary log and the current position within the file are important details. To record this information for the source when taking a backup in a replication context, you can specify the `--slave-info` option.

Prior to MySQL 5.0, a similar capability was available, known as the update log. In MySQL 5.0 and higher, the binary log replaces the update log.
See Also binlog, MySQL Enterprise Backup, replication.

binlog
An informal name for the **binary log** file. For example, you might see this abbreviation used in e-mail messages or forum discussions.
See Also binary log.

blind query expansion
A special mode of **full-text search** enabled by the `WITH QUERY EXPANSION` clause. It performs the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. This technique is mainly applicable for short search phrases, perhaps only a single word. It can uncover relevant matches where the precise search term does not occur in the document.
See Also full-text search.

**BLOB**

An SQL data type (TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB) for objects containing any kind of binary data, of arbitrary size. Used for storing documents, images, sound files, and other kinds of information that cannot easily be decomposed to rows and columns within a MySQL table. The techniques for handling BLOBs within a MySQL application vary with each Connector and API. MySQL Connector/ODBC defines BLOB values as LONGVARBINARY. For large, free-form collections of character data, the industry term is CLOB, represented by the MySQL TEXT data types.

See Also API, CLOB, connector, Connector/ODBC.

**bottleneck**

A portion of a system that is constrained in size or capacity, that has the effect of limiting overall throughput. For example, a memory area might be smaller than necessary; access to a single required resource might prevent multiple CPU cores from running simultaneously; or waiting for disk I/O to complete might prevent the CPU from running at full capacity. Removing bottlenecks tends to improve concurrency. For example, the ability to have multiple InnoDB buffer pool instances reduces contention when multiple sessions read from and write to the buffer pool simultaneously.

See Also buffer pool, concurrency.

**bounce**

A shutdown operation immediately followed by a restart. Ideally with a relatively short warmup period so that performance and throughput quickly return to a high level.

See Also shutdown.

**buddy allocator**

A mechanism for managing different-sized pages in the InnoDB buffer pool.

See Also buffer pool, page, page size.

**buffer**

A memory or disk area used for temporary storage. Data is buffered in memory so that it can be written to disk efficiently, with a few large I/O operations rather than many small ones. Data is buffered on disk for greater reliability, so that it can be recovered even when a crash or other failure occurs at the worst possible time. The main types of buffers used by InnoDB are the buffer pool, the doublewrite buffer, and the change buffer.

See Also buffer pool, change buffer, crash, doublewrite buffer.

**buffer pool**

The memory area that holds cached InnoDB data for both tables and indexes. For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the LRU algorithm. On systems with large memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances.

Several InnoDB status variables, INFORMATION_SCHEMA tables, and performance_schema tables help to monitor the internal workings of the buffer pool. Starting in MySQL 5.6, you can avoid a lengthy warmup period after restarting the server, particularly for instances with large buffer pools, by saving the buffer pool state at server shutdown and restoring the buffer pool to the same state at server startup. See Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”.

See Also buffer pool instance, LRU, page, warm up.

**buffer pool instance**

Any of the multiple regions into which the buffer pool can be divided, controlled by the innodb_buffer_pool_instances configuration option. The total memory size specified by innodb_buffer_pool_size is divided among all buffer pool instances. Typically, having multiple buffer pool instances is appropriate for systems that allocate multiple gigabytes to the InnoDB buffer pool, with each instance being one gigabyte or larger. On systems loading or looking up large amounts of data in the buffer pool from
many concurrent sessions, having multiple buffer pool instances reduces contention for exclusive access to data structures that manage the buffer pool.

See Also buffer pool.

built-in

The built-in InnoDB storage engine within MySQL is the original form of distribution for the storage engine. Contrast with the InnoDB Plugin. Starting with MySQL 5.5, the InnoDB Plugin is merged back into the MySQL code base as the built-in InnoDB storage engine (known as InnoDB 1.1).

This distinction is important mainly in MySQL 5.1, where a feature or bug fix might apply to the InnoDB Plugin but not the built-in InnoDB, or vice versa.

See Also InnoDB.

business rules

The relationships and sequences of actions that form the basis of business software, used to run a commercial company. Sometimes these rules are dictated by law, other times by company policy. Careful planning ensures that the relationships encoded and enforced by the database, and the actions performed through application logic, accurately reflect the real policies of the company and can handle real-life situations.

For example, an employee leaving a company might trigger a sequence of actions from the human resources department. The human resources database might also need the flexibility to represent data about a person who has been hired, but not yet started work. Closing an account at an online service might result in data being removed from a database, or the data might be moved or flagged so that it could be recovered if the account is re-opened. A company might establish policies regarding salary maximums, minimums, and adjustments, in addition to basic sanity checks such as the salary not being a negative number. A retail database might not allow a purchase with the same serial number to be returned more than once, or might not allow credit card purchases above a certain value, while a database used to detect fraud might allow these kinds of things.

See Also relational.

C.cfg file

A metadata file used with the InnoDB transportable tablespace feature. It is produced by the command FLUSH TABLES ... FOR EXPORT, puts one or more tables in a consistent state that can be copied to another server. The .cfg file is copied along with the corresponding .ibd file, and used to adjust the internal values of the .ibd file, such as the space ID, during the ALTER TABLE ... IMPORT TABLESPACE step.

See Also .ibd file, space ID, transportable tablespace.

C

A programming language that combines portability with performance and access to low-level hardware features, making it a popular choice for writing operating systems, drivers, and other kinds of system software. Many complex applications, languages, and reusable modules feature pieces written in C, tied together with high-level components written in other languages. Its core syntax is familiar to C++, Java, and C# developers.

See Also C API, C++, C#, Java.

C API

The C API code is distributed with MySQL. It is included in the libmysqlclient library and enables C programs to access a database.

See Also API, C, libmysqlclient.

C#

A programming language combining strong typing and object-oriented features, running within the Microsoft .NET framework or its open-source counterpart Mono. Often used for creating applications with the ASP.net framework. Its syntax is familiar to C, C++ and Java developers.

See Also .NET, ASP, C, Connector/NET, C++, Java, Mono.
C++

A programming language with core syntax familiar to C developers. Provides access to low-level operations for performance, combined with higher-level data types, object-oriented features, and garbage collection. To write C++ applications for MySQL, you use the Connector/C++ component.

See Also C, Connector/C++.

cache

The general term for any memory area that stores copies of data for frequent or high-speed retrieval. In InnoDB, the primary kind of cache structure is the buffer pool.

See Also buffer, buffer pool.

cardinality

The number of different values in a table column. When queries refer to columns that have an associated index, the cardinality of each column influences which access method is most efficient. For example, for a column with a unique constraint, the number of different values is equal to the number of rows in the table. If a table has a million rows but only 10 different values for a particular column, each value occurs (on average) 100,000 times. A query such as SELECT c1 FROM t1 WHERE c1 = 50; thus might return 1 row or a huge number of rows, and the database server might process the query differently depending on the cardinality of c1.

If the values in a column have a very uneven distribution, the cardinality might not be a good way to determine the best query plan. For example, SELECT c1 FROM t1 WHERE c1 = x; might return 1 row when x=50 and a million rows when x=30. In such a case, you might need to use index hints to pass along advice about which lookup method is more efficient for a particular query.

Cardinality can also apply to the number of distinct values present in multiple columns, as in a composite index.

See Also column, composite index, index, index hint, persistent statistics, random dive, selectivity, unique constraint.

change buffer

A special data structure that records changes to pages in secondary indexes. These values could result from SQL INSERT, UPDATE, or DELETE statements (DML). The set of features involving the change buffer is known collectively as change buffering, consisting of insert buffering, delete buffering, and purge buffering.

Changes are only recorded in the change buffer when the relevant page from the secondary index is not in the buffer pool. When the relevant index page is brought into the buffer pool while associated changes are still in the change buffer, the changes for that page are applied in the buffer pool (merged) using the data from the change buffer. Periodically, the purge operation that runs during times when the system is mostly idle, or during a slow shutdown, writes the new index pages to disk. The purge operation can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Physically, the change buffer is part of the system tablespace, so that the index changes remain buffered across database restarts. The changes are only applied (merged) when the pages are brought into the buffer pool due to some other read operation.

The kinds and amount of data stored in the change buffer are governed by the innodb_change_buffering and innodb_change_buffer_max_size configuration options. To see information about the current data in the change buffer, issue the SHOW ENGINE INNODB STATUS command.

Formerly known as the insert buffer.

See Also buffer pool, change buffering, delete buffering, DML, insert buffer, insert buffering, merge, page, purge, purge buffering, secondary index, system tablespace.

change buffering

The general term for the features involving the change buffer, consisting of insert buffering, delete buffering, and purge buffering. Index changes resulting from SQL statements, which could normally involve random I/O operations, are held back and performed periodically by a background thread. This sequence of operations

6284
can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately. Controlled by the `innodb_change_buffering` and `innodb_change_buffer_max_size` configuration options.
See Also change buffer, delete buffering, insert buffering, purge buffering.

checkpoint
As changes are made to data pages that are cached in the buffer pool, those changes are written to the data files sometime later, a process known as flushing. The checkpoint is a record of the latest changes (represented by an LSN value) that have been successfully written to the data files.
See Also buffer pool, data files, flush, fuzzy checkpointing, LSN.

checksum
In InnoDB, a validation mechanism to detect corruption when a page in a tablespace is read from disk into the InnoDB buffer pool. This feature is controlled by the `innodb_checksums` configuration option in MySQL 5.5. `innodb_checksums` is deprecated in MySQL 5.6.3, replaced by `innodb_checksum_algorithm`.

The `innochecksum` command helps diagnose corruption problems by testing the checksum values for a specified tablespace file while the MySQL server is shut down.

MySQL also uses checksums for replication purposes. For details, see the configuration options `binlog_checksum`, `source_verify_checksum` or `master_verify_checksum`, and `replica_sql_verify_checksum` or `slave_sql_verify_checksum`.
See Also buffer pool, page, tablespace.

clean page
A page in the InnoDB buffer pool where all changes made in memory have also been written (flushed) to the data files. The opposite of a dirty page.
See Also buffer pool, data files, dirty page, flush, page.

clean shutdown
A shutdown that completes without errors and applies all changes to InnoDB tables before finishing, as opposed to a crash or a fast shutdown. Synonym for slow shutdown.
See Also crash, fast shutdown, shutdown, slow shutdown.

client
A program that runs outside the database server, communicating with the database by sending requests through a Connector, or an API made available through client libraries. It can run on the same physical machine as the database server, or on a remote machine connected over a network. It can be a special-purpose database application, or a general-purpose program like the `mysql` command-line processor.
See Also API, client libraries, connector, mysql, server.

client libraries
Files containing collections of functions for working with databases. By compiling your program with these libraries, or installing them on the same system as your application, you can run a database application (known as a client) on a machine that does not have the MySQL server installed; the application accesses the database over a network. With MySQL, you can use the `libmysqIClient` library from the MySQL server itself.
See Also client, libmysqIClient.
client-side prepared statement

A type of prepare statement where the caching and reuse are managed locally, emulating the functionality of server-side prepared statements. Historically, used by some Connector/J, Connector/ODBC, and Connector/PHP developers to work around issues with server-side stored procedures. With modern MySQL server versions, server-side prepared statements are recommended for performance, scalability, and memory efficiency.

See Also Connector/J, Connector/ODBC, Connector/PHP, prepared statement.

CLOB

An SQL data type (TINYTEXT, TEXT, MEDIUMTEXT, or LONGTEXT) for objects containing any kind of character data, of arbitrary size. Used for storing text-based documents, with associated character set and collation order. The techniques for handling CLOBs within a MySQL application vary with each Connector and API. MySQL Connector/ODBC defines TEXT values as LONGVARCHAR. For storing binary data, the equivalent is the BLOB type.

See Also API, BLOB, connector, Connector/ODBC.

clustered index

The InnoDB term for a primary key index. InnoDB table storage is organized based on the values of the primary key columns, to speed up queries and sorts involving the primary key columns. For best performance, choose the primary key columns carefully based on the most performance-critical queries. Because modifying the columns of the clustered index is an expensive operation, choose primary columns that are rarely or never updated.

In the Oracle Database product, this type of table is known as an index-organized table.

See Also index, primary key, secondary index.

cold backup

A backup taken while the database is shut down. For busy applications and websites, this might not be practical, and you might prefer a warm backup or a hot backup.

See Also backup, hot backup, warm backup.

column

A data item within a row, whose storage and semantics are defined by a data type. Each table and index is largely defined by the set of columns it contains.

Each column has a cardinality value. A column can be the primary key for its table, or part of the primary key. A column can be subject to a unique constraint, a NOT NULL constraint, or both. Values in different columns, even across different tables, can be linked by a foreign key relationship.

In discussions of MySQL internal operations, sometimes field is used as a synonym.

See Also cardinality, foreign key, index, NOT NULL constraint, primary key, row, table, unique constraint.

column index

An index on a single column.

See Also composite index, index.

column prefix

When an index is created with a length specification, such as CREATE INDEX idx ON t1 (c1(N)), only the first N characters of the column value are stored in the index. Keeping the index prefix small makes the index compact, and the memory and disk I/O savings help performance. (Although making the index prefix too small can hinder query optimization by making rows with different values appear to the query optimizer to be duplicates.)

For columns containing binary values or long text strings, where sorting is not a major consideration and storing the entire value in the index would waste space, the index automatically uses the first N (typically 768) characters of the value to do lookups and sorts.
See Also index.

**command interceptor**

Synonym for **statement interceptor**. One aspect of the **interceptor** design pattern available for both **Connector/NET** and **Connector/J**. What **Connector/NET** calls a command, **Connector/J** refers to as a statement. Contrast with **exception interceptor**.

See Also **Connector/J**, **Connector/NET**, **exception interceptor**, **interceptor**, **statement interceptor**.

**commit**

A **SQL** statement that ends a **transaction**, making permanent any changes made by the transaction. It is the opposite of **rollback**, which undoes any changes made in the transaction.

**InnoDB** uses an **optimistic** mechanism for commits, so that changes can be written to the data files before the commit actually occurs. This technique makes the commit itself faster, with the tradeoff that more work is required in case of a rollback.

By default, MySQL uses the **autocommit** setting, which automatically issues a commit following each **SQL** statement.

See Also **autocommit**, **optimistic**, **rollback**, **SQL**, **transaction**.

**compact row format**

A **row format** for **InnoDB** tables. It was the default row format from MySQL 5.0.3 to MySQL 5.7.8. In MySQL 8.0, the default row format is defined by the **innodb_default_row_format** configuration option, which has a default setting of **DYNAMIC**. The **COMPACT** row format provides a more compact representation for nulls and variable-length columns than the **REDUNDANT** row format.

For additional information about **InnoDB COMPACT row format**, see Section 17.10, "InnoDB Row Formats".

See Also **dynamic row format**, **file format**, **redundant row format**, **row format**.

**composite index**

An **index** that includes multiple columns.

See Also **index**.

**compressed backup**

The compression feature of the **MySQL Enterprise Backup** product makes a compressed copy of each **tablespace**, changing the extension from **.ibd** to **.ibz**. Compressing backup data allows you to keep more backups on hand, and reduces the time to transfer backups to a different server. The data is uncompressed during the restore operation. When a compressed backup operation processes a table that is already compressed, it skips the compression step for that table, because compressing again would result in little or no space savings.

A set of files produced by the **MySQL Enterprise Backup** product, where each **tablespace** is compressed. The compressed files are renamed with a **.ibz** file extension.

Applying **compression** at the start of the backup process helps to avoid storage overhead during the compression process, and to avoid network overhead when transferring the backup files to another server. The process of applying the **binary log** takes longer, and requires uncompressing the backup files.

See Also **apply**, **binary log**, **compression**, **hot backup**, **MySQL Enterprise Backup**, **tablespace**.

**compressed row format**

A **row format** that enables data and index **compression** for **InnoDB** tables. Large fields are stored away from the page that holds the rest of the row data, as in **dynamic row format**. Both index pages and the large fields are compressed, yielding memory and disk savings. Depending on the structure of the data, the decrease in memory and disk usage might or might not outweigh the performance overhead of uncompressing the data as it is used.

See Section 17.9, "InnoDB Table and Page Compression" for usage details.
For additional information about `InnoDB COMPRESSED` row format, see DYNAMIC Row Format. See Also compression, dynamic row format, row format.

Compressed table
A table for which the data is stored in compressed form. For `InnoDB`, it is a table created with `ROW_FORMAT=COMPRESSED`. See Section 17.9, “InnoDB Table and Page Compression” for more information. See Also compressed row format, compression.

Compressed row format
A feature with wide-ranging benefits from using less disk space, performing less I/O, and using less memory for caching.

InnoDB supports both table-level and page-level compression. InnoDB page compression is also referred to as transparent page compression. For more information about InnoDB compression, see Section 17.9, “InnoDB Table and Page Compression”.

Another type of compression is the compressed backup feature of the MySQL Enterprise Backup product. See Also buffer pool, compressed backup, compressed row format, DML, transparent page compression.

Compressed backup failure
Not actually an error, rather an expensive operation that can occur when using compression in combination with DML operations. It occurs when updates to a compressed page overflow the area on the page reserved for recording modifications; the page is compressed again, with all changes applied to the table data; the re-compressed data does not fit on the original page, requiring MySQL to split the data into two new pages and compress each one separately. To check the frequency of this condition, query the `INFORMATION_SCHEMA.INNODB_CMP` table and check how much the value of the `COMPRESS_OPS` column exceeds the value of the `COMPRESS_OPS_OK` column. Ideally, compression failures do not occur often; when they do, you can adjust the `innodb_compression_level`, `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` configuration options. See Also compression, DML, page.

Concatenated index
See composite index.

Concurrency
The ability of multiple operations (in database terminology, transactions) to run simultaneously, without interfering with each other. Concurrency is also involved with performance, because ideally the protection for multiple simultaneous transactions works with a minimum of performance overhead, using efficient mechanisms for locking. See Also ACID, locking, transaction.

Configuration file
The file that holds the option values used by MySQL at startup. Traditionally, on Linux and Unix this file is named `my.cnf`, and on Windows it is named `my.ini`. You can set a number of options related to InnoDB under the `[mysqld]` section of the file.

See Section 6.2.2.2, “Using Option Files” for information about where MySQL searches for configuration files.

When you use the MySQL Enterprise Backup product, you typically use two configuration files: one that specifies where the data comes from and how it is structured (which could be the original configuration file for your server), and a stripped-down one containing only a small set of options that specify where the backup data goes and how it is structured. The configuration files used with the MySQL Enterprise Backup product must contain certain options that are typically left out of regular configuration files, so you might need to add options to your existing configuration file for use with MySQL Enterprise Backup.
See Also *my.cnf*, MySQL Enterprise Backup, option, option file.

connection
The communication channel between an application and a MySQL server. The performance and scalability of a database applications is influenced by on how quickly a database connection can be established, how many can be made simultaneously, and how long they persist. The parameters such as host, port, and so on are represented as a **connection string** in Connector/NET, and as a DSN in Connector/ODBC. High-traffic systems make use of an optimization known as the **connection pool**.
See Also connection pool, connection string, Connector/NET, Connector/ODBC, DSN, host, port.

connection pool
A cache area that allows database connections to be reused within the same application or across different applications, rather than setting up and tearing down a new connection for every database operation. This technique is common with J2EE application servers. Java applications using Connector/J can use the connection pool features of Tomcat and other application servers. The reuse is transparent to applications; the application still opens and closes the connection as usual.
See Also connection, Connector/J, J2EE, Tomcat.

connection string
A representation of the parameters for a database connection, encoded as a string literal so that it can be used in program code. The parts of the string represent connection parameters such as host and port. A connection string contains several key-value pairs, separated by semicolons. Each key-value pair is joined with an equal sign. Frequently used with Connector/NET applications; see Creating a Connector/NET Connection String for details.
See Also connection, Connector/NET, host, port.

connector
MySQL Connectors provide connectivity to the MySQL server for client programs. Several programming languages and frameworks each have their own associated Connector. Contrast with the lower-level access provided by an API.
See Also API, client, Connector/C++, Connector/J, Connector/NET, Connector/ODBC.

Connector/C++
Connector/C++ 8.0 can be used to access MySQL servers that implement a document store, or in a traditional way using SQL queries. It enables development of C++ applications using X DevAPI, or plain C applications using X DevAPI for C. It also enables development of C++ applications that use the legacy JDBC-based API from Connector/C++ 1.1. For more information, see MySQL Connector/C++ 8.4 Developer Guide.
See Also client, connector, JDBC.

Connector/J
A JDBC driver that provides connectivity for client applications developed in the Java programming language. MySQL Connector/J is a JDBC Type 4 driver: a pure-Java implementation of the MySQL protocol that does not rely on the MySQL client libraries. For full details, see MySQL Connector/J Developer Guide.
See Also client, client libraries, connector, Java, JDBC.

Connector/NET
A MySQL connector for developers writing applications using languages, technologies, and frameworks such as C#, .NET, Mono, Visual Studio, ASP.net, and ADO.net.
See Also ADO.NET, ASP.net, connector, C#, Mono, Visual Studio.

Connector/ODBC
The family of MySQL ODBC drivers that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. Formerly called MyODBC drivers. For full details, see MySQL Connector/ODBC Developer Guide.
See Also connector, ODBC.
Connector/PHP

A version of the mysql and mysqli APIs for PHP optimized for the Windows operating system.
See Also connector, PHP, PHP API.

consistent read

A read operation that uses snapshot information to present query results based on a point in time, regardless of changes performed by other transactions running at the same time. If queried data has been changed by another transaction, the original data is reconstructed based on the contents of the undo log. This technique avoids some of the locking issues that can reduce concurrency by forcing transactions to wait for other transactions to finish.

With REPEATABLE READ isolation level, the snapshot is based on the time when the first read operation is performed. With READ COMMITTED isolation level, the snapshot is reset to the time of each consistent read operation.

Consistent read is the default mode in which InnoDB processes SELECT statements in READ COMMITTED and REPEATABLE READ isolation levels. Because a consistent read does not set any locks on the tables it accesses, other sessions are free to modify those tables while a consistent read is being performed on the table.

For technical details about the applicable isolation levels, see Section 17.7.2.3, “Consistent Nonlocking Reads”. See Also concurrency, isolation level, locking, READ COMMITTED, REPEATABLE READ, snapshot, transaction, undo log.

constraint

An automatic test that can block database changes to prevent data from becoming inconsistent. (In computer science terms, a kind of assertion related to an invariant condition.) Constraints are a crucial component of the ACID philosophy, to maintain data consistency. Constraints supported by MySQL include FOREIGN KEY constraints and unique constraints.
See Also ACID, foreign key, unique constraint.

counter

A value that is incremented by a particular kind of InnoDB operation. Useful for measuring how busy a server is, troubleshooting the sources of performance issues, and testing whether changes (for example, to configuration settings or indexes used by queries) have the desired low-level effects. Different kinds of counters are available through Performance Schema tables and INFORMATION_SCHEMA tables, particularly INFORMATION_SCHEMA.INNODB_METRICS.
See Also INFORMATION_SCHEMA, metrics counter, Performance Schema.

covering index

An index that includes all the columns retrieved by a query. Instead of using the index values as pointers to find the full table rows, the query returns values from the index structure, saving disk I/O. InnoDB can apply this optimization technique to more indexes than MyISAM can, because InnoDB secondary indexes also include the primary key columns. InnoDB cannot apply this technique for queries against tables modified by a transaction, until that transaction ends.

Any column index or composite index could act as a covering index, given the right query. Design your indexes and queries to take advantage of this optimization technique wherever possible.
See Also column index, composite index, index, primary key, secondary index.

CPU-bound

A type of workload where the primary bottleneck is CPU operations in memory. Typically involves read-intensive operations where the results can all be cached in the buffer pool.
See Also bottleneck, buffer pool, workload.

crash

MySQL uses the term “crash” to refer generally to any unexpected shutdown operation where the server cannot do its normal cleanup. For example, a crash could happen due to a hardware fault on the database server.
machine or storage device; a power failure; a potential data mismatch that causes the MySQL server to halt; a **fast shutdown** initiated by the DBA; or many other reasons. The robust, automatic **crash recovery** for **InnoDB** tables ensures that data is made consistent when the server is restarted, without any extra work for the DBA. See Also **crash recovery**, **fast shutdown**, **InnoDB**, **shutdown**.

**crash recovery**  
The cleanup activities that occur when MySQL is started again after a **crash**. For **InnoDB** tables, changes from incomplete transactions are replayed using data from the **redo log**. Changes that were **committed** before the crash, but not yet written into the **data files**, are reconstructed from the **doublewrite buffer**. When the database is shut down normally, this type of activity is performed during shutdown by the **purge** operation.

During normal operation, committed data can be stored in the **change buffer** for a period of time before being written to the data files. There is always a tradeoff between keeping the data files up-to-date, which introduces performance overhead during normal operation, and buffering the data, which can make shutdown and crash recovery take longer. See Also **change buffer**, **commit**, **crash**, **data files**, **doublewrite buffer**, **InnoDB**, **purge**, **redo log**.

**CRUD**  
Acronym for “create, read, update, delete”, a common sequence of operations in database applications. Often denotes a class of applications with relatively simple database usage (basic **DDL**, **DML** and **query** statements in **SQL**) that can be implemented quickly in any language. See Also **DDL**, **DML**, **query**, **SQL**.

**cursor**  
An internal MySQL data structure that represents the result set of an SQL statement. Often used with **prepared statements** and **dynamic SQL**. It works like an iterator in other high-level languages, producing each value from the result set as requested.

Although SQL usually handles the processing of cursors for you, you might delve into the inner workings when dealing with performance-critical code. See Also **dynamic SQL**, **prepared statement**, **query**.

**D**

**data definition language**  
See **DDL**.

**data dictionary**  
Metadata that keeps track of database objects such as **tables**, **indexes**, and table **columns**. For the MySQL data dictionary, introduced in MySQL 8.0, metadata is physically located in **InnoDB file-per-table** tablespace files in the **mysql** database directory. For the **InnoDB** data dictionary, metadata is physically located in the **InnoDB system tablespace**.

Because the **MySQL Enterprise Backup** product always backs up the **InnoDB** system tablespace, all backups include the contents of the **InnoDB** data dictionary. See Also **column**, **file-per-table**, **.frm file**, **index**, **MySQL Enterprise Backup**, **system tablespace**, **table**.

**data directory**  
The directory under which each MySQL **instance** keeps the **data files** for **InnoDB** and the directories representing individual databases. Controlled by the **datadir** configuration option. See Also **data files**, **instance**.

**data files**  
The files that physically contain **table** and **index** data.
The **InnoDB system tablespace**, which holds the **InnoDB data dictionary** and is capable of holding data for multiple **InnoDB** tables, is represented by one or more `.ibdata` data files.

File-per-table tablespaces, which hold data for a single **InnoDB** table, are represented by a `.ibd` data file.

General tablespaces (introduced in MySQL 5.7.6), which can hold data for multiple **InnoDB** tables, are also represented by a `.ibd` data file.

See Also **data dictionary**, **file-per-table**, **general tablespace**, `.ibd` file, `ibdata` file, index, system tablespace, table, tablespace.

data manipulation language

See **DML**.

data warehouse

A database system or application that primarily runs large queries. The read-only or read-mostly data might be organized in **denormalized** form for query efficiency. Can benefit from the optimizations for **read-only transactions** in MySQL 5.6 and higher. Contrast with **OLTP**.

See Also **denormalized**, **OLTP**, query, read-only transaction.

database

Within the MySQL **data directory**, each database is represented by a separate directory. The **InnoDB system tablespace**, which can hold table data from multiple databases within a MySQL instance, is kept in data files that reside outside of individual database directories. When **file-per-table** mode is enabled, the `.ibd` files representing individual InnoDB tables are stored inside the database directories unless created elsewhere using the **DATA DIRECTORY** clause. General tablespaces, introduced in MySQL 5.7.6, also hold table data in `.ibd` files. Unlike file-per-table `.ibd` files, general tablespace `.ibd` files can hold table data from multiple databases within a MySQL instance, and can be assigned to directories relative to or independent of the MySQL data directory.

For long-time MySQL users, a database is a familiar notion. Users coming from an Oracle Database background may find that the MySQL meaning of a database is closer to what Oracle Database calls a **schema**.

See Also **data files**, **file-per-table**, `.ibd` file, instance, schema, system tablespace.

DCL

Data control language, a set of **SQL** statements for managing privileges. In MySQL, consists of the **GRANT** and **REVOKE** statements. Contrast with **DDL** and **DML**.

See Also **DDL**, **DML**, **SQL**.

DDEX provider

A feature that lets you use the data design tools within **Visual Studio** to manipulate the schema and objects within a MySQL database. For MySQL applications using **Connector.NET**, the MySQL Visual Studio Plugin acts as a DDEX provider with MySQL 5.0 and later.

See Also **Visual Studio**.

DDL

Data definition language, a set of **SQL** statements for manipulating the database itself rather than individual table rows. Includes all forms of the **CREATE**, **ALTER**, and **DROP** statements. Also includes the **TRUNCATE** statement, because it works differently than a **DELETE FROM** `table_name` statement, even though the ultimate effect is similar.

DDL statements automatically commit the current transaction; they cannot be rolled back.

The **InnoDB online DDL** feature enhances performance for **CREATE INDEX**, **DROP INDEX**, and many types of **ALTER TABLE** operations. See **Section 17.12, “InnoDB and Online DDL”** for more information. Also, the **InnoDB file-per-table** setting can affect the behavior of **DROP TABLE** and **TRUNCATE TABLE** operations.

Contrast with **DML** and **DCL**.
deadlock
A situation where different transactions are unable to proceed, because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither one ever releases the locks it holds.

A deadlock can occur when the transactions lock rows in multiple tables (through statements such as UPDATE or SELECT . . . FOR UPDATE), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue.

For background information on how deadlocks are automatically detected and handled, see Section 17.7.5.2, “Deadlock Detection”. For tips on avoiding and recovering from deadlock conditions, see Section 17.7.5.3, “How to Minimize and Handle Deadlocks”.

See Also gap, lock, transaction.

deadlock detection
A mechanism that automatically detects when a deadlock occurs, and automatically rolls back one of the transactions involved (the victim). Deadlock detection can be disabled using the innodb_deadlock_detect configuration option.

See Also deadlock, rollback, transaction, victim.

delete
When InnoDB processes a DELETE statement, the rows are immediately marked for deletion and no longer are returned by queries. The storage is reclaimed sometime later, during the periodic garbage collection known as the purge operation. For removing large quantities of data, related operations with their own performance characteristics are TRUNCATE and DROP.

See Also drop, purge, truncate.

delete buffering
The technique of storing changes to secondary index pages, resulting from DELETE operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally marks an index record for deletion.) It is one of the types of change buffering; the others are insert buffering and purge buffering.

See Also change buffer, change buffering, insert buffer, insert buffering, purge buffering.

denormalized
A data storage strategy that duplicates data across different tables, rather than linking the tables with foreign keys and join queries. Typically used in data warehouse applications, where the data is not updated after loading. In such applications, query performance is more important than making it simple to maintain consistent data during updates. Contrast with normalized.

See Also data warehouse, foreign key, join, normalized.

descending index
A type of index where index storage is optimized to process ORDER BY column DESC clauses.

See Also index.

dictionary object cache
The dictionary object cache stores previously accessed data dictionary objects in memory to enable object reuse and minimize disk I/O. An LRU-based eviction strategy is used to evict least recently used objects from memory. The cache is comprised of several partitions that store different object types.

For more information, see Section 16.4, “Dictionary Object Cache”.

dirty page

A page in the InnoDB buffer pool that has been updated in memory, where the changes are not yet written (flushed) to the data files. The opposite of a clean page.

See Also buffer pool, clean page, data files, flush, page.

dirty read

An operation that retrieves unreliable data, data that was updated by another transaction but not yet committed. It is only possible with the isolation level known as read uncommitted.

This kind of operation does not adhere to the ACID principle of database design. It is considered very risky, because the data could be rolled back, or updated further before being committed; then, the transaction doing the dirty read would be using data that was never confirmed as accurate.

Its opposite is consistent read, where InnoDB ensures that a transaction does not read information updated by another transaction, even if the other transaction commits in the meantime.

See Also ACID, commit, consistent read, isolation level, READ UNCOMMITTED, rollback.

disk-based

A kind of database that primarily organizes data on disk storage (hard drives or equivalent). Data is brought back and forth between disk and memory to be operated upon. It is the opposite of an in-memory database. Although InnoDB is disk-based, it also contains features such as the buffer pool, multiple buffer pool instances, and the adaptive hash index that allow certain kinds of workloads to work primarily from memory.

See Also adaptive hash index, buffer pool, in-memory database.

disk-bound

A type of workload where the primary bottleneck is disk I/O. (Also known as I/O-bound.) Typically involves frequent writes to disk, or random reads of more data than can fit into the buffer pool.

See Also bottleneck, buffer pool, workload.

DML

Data manipulation language, a set of SQL statements for performing INSERT, UPDATE, and DELETE operations. The SELECT statement is sometimes considered as a DML statement, because the SELECT ... FOR UPDATE form is subject to the same considerations for locking as INSERT, UPDATE, and DELETE.

DML statements for an InnoDB table operate in the context of a transaction, so their effects can be committed or rolled back as a single unit.

Contrast with DDL and DCL.

See Also commit, DCL,DDL, locking, rollback, SQL, transaction.

document id

In the InnoDB full-text search feature, a special column in the table containing the FULLTEXT index, to uniquely identify the document associated with each ilist value. Its name is FTS_DOC_ID (uppercase required). The column itself must be of BIGINT UNSIGNED NOT NULL type, with a unique index named FTS_DOC_ID_INDEX. Preferably, you define this column when creating the table. If InnoDB must add the column to the table while creating a FULLTEXT index, the indexing operation is considerably more expensive.

See Also full-text search, FULLTEXT index, ilist.

doublewrite buffer

InnoDB uses a file flush technique called doublewrite. Before writing pages to the data files, InnoDB first writes them to a storage area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer have completed, does InnoDB write the pages to their proper positions in the data file. If there is an operating system, storage subsystem or mysqld process crash in the middle of a page write, InnoDB can find a good copy of the page from the doublewrite buffer during crash recovery.
Although data is always written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the buffer itself as a large sequential chunk, with a single `fsync()` call to the operating system.
See Also crash recovery, data files, page, purge.

drop
A kind of DDL operation that removes a schema object, through a statement such as `DROP TABLE` or `DROP INDEX`. It maps internally to an `ALTER TABLE` statement. From an InnoDB perspective, the performance considerations of such operations involve the time that the data dictionary is locked to ensure that interrelated objects are all updated, and the time to update memory structures such as the buffer pool. For a table, the drop operation has somewhat different characteristics than a `truncate` operation (`TRUNCATE TABLE` statement).
See Also buffer pool, data dictionary, DDL, table, truncate.

DSN
Acronym for “Database Source Name”. It is the encoding for connection information within Connector/ODBC.
See Configuring a Connector/ODBC DSN on Windows for full details. It is the equivalent of the connection string used by Connector/NET.
See Also connection, connection string, Connector/NET, Connector/ODBC.

dynamic cursor
A type of cursor supported by ODBC that can pick up new and changed results when the rows are read again. Whether and how quickly the changes are visible to the cursor depends on the type of table involved (transactional or non-transactional) and the isolation level for transactional tables. Support for dynamic cursors must be explicitly enabled.
See Also cursor, ODBC.

dynamic row format
An InnoDB row format. Because long variable-length column values are stored outside of the page that holds the row data, it is very efficient for rows that include large objects. Since the large fields are typically not accessed to evaluate query conditions, they are not brought into the buffer pool as often, resulting in fewer I/O operations and better utilization of cache memory.

As of MySQL 5.7.9, the default row format is defined by `innodb_default_row_format`, which has a default value of `DYNAMIC`.

For additional information about InnoDB DYNAMIC row format, see DYNAMIC Row Format.
See Also buffer pool, file format, row format.

dynamic SQL
A feature that lets you create and execute prepared statements using more robust, secure, and efficient methods to substitute parameter values than the naive technique of concatenating the parts of the statement into a string variable.
See Also prepared statement.

dynamic statement
A prepared statement created and executed through dynamic SQL.
See Also dynamic SQL, prepared statement.

E

early adopter
A stage similar to beta, when a software product is typically evaluated for performance, functionality, and compatibility in a non-mission-critical setting.
See Also beta.
Eiffel
A programming language including many object-oriented features. Some of its concepts are familiar to Java and C# developers. For the open-source Eiffel API for MySQL, see Section 31.13, “MySQL Eiffel Wrapper”. See Also API, C#, Java.

embedded
The embedded MySQL server library (libmysqld) makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications. See Also client, libmysqld.

error log
A type of log showing information about MySQL startup and critical runtime errors and crash information. For details, see Section 7.4.2, “The Error Log”. See Also crash, log.

eviction
The process of removing an item from a cache or other temporary storage area, such as the InnoDB buffer pool. Often, but not always, uses the LRU algorithm to determine which item to remove. When a dirty page is evicted, its contents are flushed to disk, and any dirty neighbor pages might be flushed also. See Also buffer pool, dirty page, flush, LRU, neighbor page.

exception interceptor
A type of interceptor for tracing, debugging, or augmenting SQL errors encountered by a database application. For example, the interceptor code could issue a SHOW WARNINGS statement to retrieve additional information, and add descriptive text or even change the type of the exception returned to the application. Because the interceptor code is only called when SQL statements return errors, it does not impose any performance penalty on the application during normal (error-free) operation.

In Java applications using Connector/J, setting up this type of interceptor involves implementing the com.mysql.jdbc.ExceptionInterceptor interface, and adding a exceptionInterceptors property to the connection string.

In Visual Studio applications using Connector/NET, setting up this type of interceptor involves defining a class that inherits from the BaseExceptionInterceptor class and specifying that class name as part of the connection string. See Also Connector/J, Connector/NET, interceptor, Java, Visual Studio.

exclusive lock
A kind of lock that prevents any other transaction from locking the same row. Depending on the transaction isolation level, this kind of lock might block other transactions from writing to the same row, or might also block other transactions from reading the same row. The default InnoDB isolation level, REPEATABLE READ, enables higher concurrency by allowing transactions to read rows that have exclusive locks, a technique known as consistent read. See Also concurrency, consistent read, isolation level, lock, REPEATABLE READ, shared lock, transaction.

extent
A group of pages within a tablespace. For the default page size of 16KB, an extent contains 64 pages. In MySQL 5.6, the page size for an InnoDB instance can be 4KB, 8KB, or 16KB, controlled by the innodb_page_size configuration option. For 4KB, 8KB, and 16KB pages sizes, the extent size is always 1MB (or 1048576 bytes).

Support for 32KB and 64KB InnoDB page sizes was added in MySQL 5.7.6. For a 32KB page size, the extent size is 2MB. For a 64KB page size, the extent size is 4MB. InnoDB features such as segments, read-ahead requests and the doublewrite buffer use I/O operations that read, write, allocate, or free data one extent at a time.
See Also doublewrite buffer, page, page size, read-ahead, segment, tablespace.

F

.frm file
A file containing the metadata, such as the table definition, of a MySQL table. .frm files were removed in MySQL 8.0 but are still used in earlier MySQL releases. In MySQL 8.0, data previously stored in .frm files is stored in data dictionary tables.
See Also data dictionary, MySQL Enterprise Backup, system tablespace.

failover
The ability to automatically switch to a standby server in the event of a failure. In the MySQL context, failover involves a standby database server. Often supported within J2EE environments by the application server or framework.
See Also Connector/J, J2EE.

Fast Index Creation
A capability first introduced in the InnoDB Plugin, now part of MySQL in 5.5 and higher, that speeds up creation of InnoDB secondary indexes by avoiding the need to completely rewrite the associated table. The speedup applies to dropping secondary indexes also.

Because index maintenance can add performance overhead to many data transfer operations, consider doing operations such as ALTER TABLE ... ENGINE=INNODB or INSERT INTO ... SELECT * FROM ... without any secondary indexes in place, and creating the indexes afterward.

In MySQL 5.6, this feature becomes more general. You can read and write to tables while an index is being created, and many more kinds of ALTER TABLE operations can be performed without copying the table, without blocking DML operations, or both. Thus in MySQL 5.6 and higher, this set of features is referred to as online DDL rather than Fast Index Creation.

For related information, see Section 17.12, “InnoDB and Online DDL”.
See Also DML, index, online DDL, secondary index.

fast shutdown
The default shutdown procedure for InnoDB, based on the configuration setting innodb_fast_shutdown=1. To save time, certain flush operations are skipped. This type of shutdown is safe during normal usage, because the flush operations are performed during the next startup, using the same mechanism as in crash recovery. In cases where the database is being shut down for an upgrade or downgrade, do a slow shutdown instead to ensure that all relevant changes are applied to the data files during the shutdown.
See Also crash recovery, data files, flush, shutdown, slow shutdown.

drive format
The file format for InnoDB tables.
See Also file-per-table, .ibd file, ibdata file, row format.

file-per-table
A general name for the setting controlled by the innodb_file_per_table option, which is an important configuration option that affects aspects of InnoDB file storage, availability of features, and I/O characteristics. As of MySQL 5.6.7, innodb_file_per_table is enabled by default.

With the innodb_file_per_table option enabled, you can create a table in its own .ibd file rather than in the shared ibdata files of the system tablespace. When table data is stored in an individual .ibd file, you have more flexibility to choose row formats required for features such as data compression. The TRUNCATE TABLE operation is also faster, and reclaimed space can be used by the operating system rather than remaining reserved for InnoDB.
The MySQL Enterprise Backup product is more flexible for tables that are in their own files. For example, tables can be excluded from a backup, but only if they are in separate files. Thus, this setting is suitable for tables that are backed up less frequently or on a different schedule.

See Also compressed row format, compression, file format, .ibd file, ibdata file, innodb_file_per_table, MySQL Enterprise Backup, row format, system tablespace.

fill factor
In an InnoDB index, the proportion of a page that is taken up by index data before the page is split. The unused space when index data is first divided between pages allows for rows to be updated with longer string values without requiring expensive index maintenance operations. If the fill factor is too low, the index consumes more space than needed, causing extra I/O overhead when reading the index. If the fill factor is too high, any update that increases the length of column values can cause extra I/O overhead for index maintenance. See Section 17.6.2.2, “The Physical Structure of an InnoDB Index” for more information.

See Also index, page.

fixed row format
This row format is used by the MyISAM storage engine, not by InnoDB. If you create an InnoDB table with the option ROW_FORMAT=FIXED in MySQL 5.7.6 or earlier, InnoDB uses the compact row format instead, although the FIXED value might still show up in output such as SHOW TABLE STATUS reports. As of MySQL 5.7.7, InnoDB returns an error if ROW_FORMAT=FIXED is specified.

See Also compact row format, row format.

flush
To write changes to the database files, that had been buffered in a memory area or a temporary disk storage area. The InnoDB storage structures that are periodically flushed include the redo log, the undo log, and the buffer pool.

Flushing can happen because a memory area becomes full and the system needs to free some space, because a commit operation means the changes from a transaction can be finalized, or because a slow shutdown operation means that all outstanding work should be finalized. When it is not critical to flush all the buffered data at once, InnoDB can use a technique called fuzzy checkpointing to flush small batches of pages to spread out the I/O overhead.

See Also buffer pool, commit, fuzzy checkpointing, redo log, slow shutdown, undo log.

flush list
An internal InnoDB data structure that tracks dirty pages in the buffer pool: that is, pages that have been changed and need to be written back out to disk. This data structure is updated frequently by InnoDB internal mini-transactions, and so is protected by its own mutex to allow concurrent access to the buffer pool.

See Also buffer pool, dirty page, LRU, mini-transaction, mutex, page, page cleaner.

foreign key
A type of pointer relationship, between rows in separate InnoDB tables. The foreign key relationship is defined on one column in both the parent table and the child table.

In addition to enabling fast lookup of related information, foreign keys help to enforce referential integrity, by preventing any of these pointers from becoming invalid as data is inserted, updated, and deleted. This enforcement mechanism is a type of constraint. A row that points to another table cannot be inserted if the associated foreign key value does not exist in the other table. If a row is deleted or its foreign key value changed, and rows in another table point to that foreign key value, the foreign key can be set up to prevent the deletion, cause the corresponding column values in the other table to become null, or automatically delete the corresponding rows in the other table.

One of the stages in designing a normalized database is to identify data that is duplicated, separate that data into a new table, and set up a foreign key relationship so that the multiple tables can be queried like a single table, using a join operation.
See Also child table, FOREIGN KEY constraint, join, normalized, NULL, parent table, referential integrity, relational.

FOREIGN KEY constraint
The type of constraint that maintains database consistency through a foreign key relationship. Like other kinds of constraints, it can prevent data from being inserted or updated if data would become inconsistent; in this case, the inconsistency being prevented is between data in multiple tables. Alternatively, when a DML operation is performed, FOREIGN KEY constraints can cause data in child rows to be deleted, changed to different values, or set to null, based on the ON CASCADE option specified when creating the foreign key.
See Also child table, constraint, DML, foreign key, NULL.

FTS
In most contexts, an acronym for full-text search. Sometimes in performance discussions, an acronym for full table scan.
See Also full table scan, full-text search.

full backup
A backup that includes all the tables in each MySQL database, and all the databases in a MySQL instance. Contrast with partial backup.
See Also backup, database, instance, partial backup, table.

full table scan
An operation that requires reading the entire contents of a table, rather than just selected portions using an index. Typically performed either with small lookup tables, or in data warehousing situations with large tables where all available data is aggregated and analyzed. How frequently these operations occur, and the sizes of the tables relative to available memory, have implications for the algorithms used in query optimization and managing the buffer pool.

The purpose of indexes is to allow lookups for specific values or ranges of values within a large table, thus avoiding full table scans when practical.
See Also buffer pool, index.

full-text search
The MySQL feature for finding words, phrases, Boolean combinations of words, and so on within table data, in a faster, more convenient, and more flexible way than using the SQL LIKE operator or writing your own application-level search algorithm. It uses the SQL function MATCH() and FULLTEXT indexes.
See Also FULLTEXT index.

FULLTEXT index
The special kind of index that holds the search index in the MySQL full-text search mechanism. Represents the words from values of a column, omitting any that are specified as stopwords. Originally, only available for MyISAM tables. Starting in MySQL 5.6.4, it is also available for InnoDB tables.
See Also full-text search, index, InnoDB, search index, stopword.

fuzzy checkpointing
A technique that flushes small batches of dirty pages from the buffer pool, rather than flushing all dirty pages at once which would disrupt database processing.
See Also buffer pool, dirty page, flush.

G

GA
“Generally available”, the stage when a software product leaves beta and is available for sale, official support, and production use.
See Also beta.

GAC
Acronym for “Global Assembly Cache”. A central area for storing libraries (assemblies) on a .NET system. Physically consists of nested folders, treated as a single virtual folder by the .NET CLR.
See Also .NET, assembly.

gap
A place in an InnoDB index data structure where new values could be inserted. When you lock a set of rows with a statement such as SELECT ... FOR UPDATE, InnoDB can create locks that apply to the gaps as well as the actual values in the index. For example, if you select all values greater than 10 for update, a gap lock prevents another transaction from inserting a new value that is greater than 10. The supremum record and infimum record represent the gaps containing all values greater than or less than all the current index values.
See Also concurrency, gap lock, index, infimum record, isolation level, supremum record.

gap lock
A lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE;` prevents other transactions from inserting a value of 15 into the column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked. Contrast with record lock and next-key lock.
Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.
See Also gap, infimum record, lock, next-key lock, record lock, supremum record.

general log
See general query log.

general query log
A type of log used for diagnosis and troubleshooting of SQL statements processed by the MySQL server. Can be stored in a file or in a database table. You must enable this feature through the general_log configuration option to use it. You can disable it for a specific connection through the sql_log_off configuration option.

Records a broader range of queries than the slow query log. Unlike the binary log, which is used for replication, the general query log contains SELECT statements and does not maintain strict ordering. For more information, see Section 7.4.3, “The General Query Log”.
See Also binary log, log, slow query log.

general tablespace
A shared InnoDB tablespace created using CREATE TABLESPACE syntax. General tablespaces can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. General tablespaces were introduced in MySQL 5.7.6.

Tables are added to a general tablespace using `CREATE TABLE tbl_name ... TABLESPACE [=]` `tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=]` `tablespace_name` syntax.

Contrast with system tablespace and file-per-table tablespace.

For more information, see Section 17.6.3.3, “General Tablespaces”.
See Also file-per-table, system tablespace, table, tablespace.

generated column
A column whose values are computed from an expression included in the column definition. A generated column can be virtual or stored.
See Also base column, stored generated column, virtual generated column.
generated stored column
   See stored generated column.

generated virtual column
   See virtual generated column.

Glassfish
   See Also J2EE.

global temporary tablespace
   A temporary tablespace that stores rollback segments for changes made to user-created temporary tables.
   See Also temporary tablespace.

global transaction
   A type of transaction involved in XA operations. It consists of several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties.
   See Also ACID, transaction, XA.

group commit
   An InnoDB optimization that performs some low-level I/O operations (log write) once for a set of commit operations, rather than flushing and syncing separately for each commit.
   See Also binary log, commit.

GUID
   Acronym for “globally unique identifier”, an ID value that can be used to associate data across different databases, languages, operating systems, and so on. (As an alternative to using sequential integers, where the same values could appear in different tables, databases, and so on referring to different data.) Older MySQL versions represented it as BINARY(16). Currently, it is represented as CHAR(36). MySQL has a UUID() function that returns GUID values in character format, and a UUID_SHORT() function that returns GUID values in integer format. Because successive GUID values are not necessarily in ascending sort order, it is not an efficient value to use as a primary key for large InnoDB tables.

H

hash index
   A type of index intended for queries that use equality operators, rather than range operators such as greater-than or BETWEEN. It is available for MEMORY tables. Although hash indexes are the default for MEMORY tables for historic reasons, that storage engine also supports B-tree indexes, which are often a better choice for general-purpose queries.

MySQL includes a variant of this index type, the adaptive hash index, that is constructed automatically for InnoDB tables if needed based on runtime conditions.
   See Also adaptive hash index, B-tree, index, InnoDB.

HDD
   Acronym for “hard disk drive”. Refers to storage media using spinning platters, usually when comparing and contrasting with SSD. Its performance characteristics can influence the throughput of a disk-based workload.
   See Also disk-based, SSD.

heartbeat
   A periodic message that is sent to indicate that a system is functioning properly. In a replication context, if the source stops sending such messages, one of the replicas can take its place. Similar techniques can be used between the servers in a cluster environment, to confirm that all of them are operating properly.
high-water mark
A value representing an upper limit, either a hard limit that should not be exceeded at runtime, or a record of the maximum value that was actually reached. Contrast with low-water mark.
See Also low-water mark.

history list
A list of transactions with delete-marked records scheduled to be processed by the InnoDB purge operation. Recorded in the undo log. The length of the history list is reported by the command SHOW ENGINE INNODB STATUS. If the history list grows longer than the value of the innodb_max_purge_lag configuration option, each DML operation is delayed slightly to allow the purge operation to finish flushing the deleted records.
Also known as purge lag.
See Also DML, flush, purge, purge lag, rollback segment, transaction, undo log.

hole punching
Releasing empty blocks from a page. The InnoDB transparent page compression feature relies on hole punching support. For more information, see Section 17.9.2, “InnoDB Page Compression”.
See Also sparse file, transparent page compression.

host
The network name of a database server, used to establish a connection. Often specified in conjunction with a port. In some contexts, the IP address 127.0.0.1 works better than the special name localhost for accessing a database on the same server as the application.
See Also connection, localhost, port.

hot
A condition where a row, table, or internal data structure is accessed so frequently, requiring some form of locking or mutual exclusion, that it results in a performance or scalability issue.

Although “hot” typically indicates an undesirable condition, a hot backup is the preferred type of backup.
See Also hot backup.

hot backup
A backup taken while the database is running and applications are reading and writing to it. The backup involves more than simply copying data files: it must include any data that was inserted or updated while the backup was in process; it must exclude any data that was deleted while the backup was in process; and it must ignore any changes that were not committed.

The Oracle product that performs hot backups, of InnoDB tables especially but also tables from MyISAM and other storage engines, is known as MySQL Enterprise Backup.

The hot backup process consists of two stages. The initial copying of the data files produces a raw backup. The apply step incorporates any changes to the database that happened while the backup was running. Applying the changes produces a prepared backup; these files are ready to be restored whenever necessary.
See Also apply, MySQL Enterprise Backup, prepared backup, raw backup.

.ibd file
The data file for file-per-table tablespaces and general tablespaces. File-per-table tablespace .ibd files contain a single table and associated index data. General tablespace .ibd files may contain table and index data for multiple tables.
The `.ibd` file extension does not apply to the **system tablespace**, which consists of one or more **ibdata files**.

If a file-per-table tablespace or general tablespace is created with the `DATA DIRECTORY =` clause, the `.ibd` file is located at the specified path, outside the normal data directory.

When a `.ibd` file is included in a compressed backup by the **MySQL Enterprise Backup** product, the compressed equivalent is a `.ibz` file.

See Also database, file-per-table, general tablespace, ibdata file, .ibz file, innodb_file_per_table, MySQL Enterprise Backup, system tablespace.

**.ibz file**

When the **MySQL Enterprise Backup** product performs a **compressed backup**, it transforms each **tablespace** file that is created using the **file-per-table** setting from a `.ibd` extension to a `.ibz` extension.

The compression applied during backup is distinct from the **compressed row format** that keeps table data compressed during normal operation. A compressed backup operation skips the compression step for a tablespace that is already in compressed row format, as compressing a second time would slow down the backup but produce little or no space savings.

See Also compressed backup, compressed row format, file-per-table, .ibd file, MySQL Enterprise Backup, tablespace.

**I/O-bound**

See disk-bound.

**ib-file set**

The set of files managed by **InnoDB** within a MySQL database: the **system tablespace**, **file-per-table** tablespace files, and **redo log** files. Depending on MySQL version and **InnoDB** configuration, may also include **general tablespace**, **temporary tablespace**, and **undo tablespace** files. This term is sometimes used in detailed discussions of **InnoDB** file structures and formats to refer to the set of files managed by **InnoDB** within a MySQL database.

See Also database, file-per-table, general tablespace, redo log, system tablespace, temporary tablespace, undo tablespace.

**ibbackup_logfile**

A supplemental backup file created by the **MySQL Enterprise Backup** product during a **hot backup** operation. It contains information about any data changes that occurred while the backup was running. The initial backup files, including `ibbackup_logfile`, are known as a **raw backup**, because the changes that occurred during the backup operation are not yet incorporated. After you perform the **apply** step to the raw backup files, the resulting files do include those final data changes, and are known as a **prepared backup**. At this stage, the `ibbackup_logfile` file is no longer necessary.

See Also **apply**, hot backup, MySQL Enterprise Backup, prepared backup, raw backup.

**ibdata file**

A set of files with names such as `ibdata1`, `ibdata2`, and so on, that make up the **InnoDB system tablespace**. For information about the structures and data that reside in the system tablespace `ibdata` files, see Section 17.6.3.1, “The System Tablespace”.

Growth of the `ibdata` files is influenced by the `innodb_autoextend_increment` configuration option.

See Also change buffer, data dictionary, doublewrite buffer, file-per-table, .ibd file, innodb_file_per_table, system tablespace, undo log.

**ibtmp file**

The **InnoDB temporary tablespace data file** for non-compressed **InnoDB temporary tables** and related objects. The configuration file option, `innodb_temp_data_file_path`, allows users to define a relative path for
the temporary tablespace data file. If `innodb_temp_data_file_path` is not specified, the default behavior is to create a single auto-extending 12MB data file named `ibtmp1` in the data directory, alongside `ibdata1`. See Also data files, temporary table, temporary tablespace.

**ib_logfile**
A set of files, typically named `ib_logfile0` and `ib_logfile1`, that form the redo log. Also sometimes referred to as the log group. These files record statements that attempt to change data in InnoDB tables. These statements are replayed automatically to correct data written by incomplete transactions, on startup following a crash.

This data cannot be used for manual recovery; for that type of operation, use the binary log. See Also binary log, log group, redo log.

**ilist**
Within an InnoDB FULLTEXT index, the data structure consisting of a document ID and positional information for a token (that is, a particular word). See Also FULLTEXT index.

**implicit row lock**
A row lock that InnoDB acquires to ensure consistency, without you specifically requesting it. See Also row lock.

**in-memory database**
A type of database system that maintains data in memory, to avoid overhead due to disk I/O and translation between disk blocks and memory areas. Some in-memory databases sacrifice durability (the “D” in the ACID design philosophy) and are vulnerable to hardware, power, and other types of failures, making them more suitable for read-only operations. Other in-memory databases do use durability mechanisms such as logging changes to disk or using non-volatile memory.

MySQL features that address the same kinds of memory-intensive processing include the InnoDB buffer pool, adaptive hash index, and read-only transaction optimization, the MEMORY storage engine, the MyISAM key cache, and the MySQL query cache. See Also ACID, adaptive hash index, buffer pool, disk-based, read-only transaction.

**incremental backup**
A type of hot backup, performed by the MySQL Enterprise Backup product, that only saves data changed since some point in time. Having a full backup and a succession of incremental backups lets you reconstruct backup data over a long period, without the storage overhead of keeping several full backups on hand. You can restore the full backup and then apply each of the incremental backups in succession, or you can keep the full backup up-to-date by applying each incremental backup to it, then perform a single restore operation.

The granularity of changed data is at the page level. A page might actually cover more than one row. Each changed page is included in the backup. See Also hot backup, MySQL Enterprise Backup, page.

**index**
A data structure that provides a fast lookup capability for rows of a table, typically by forming a tree structure (B-tree) representing all the values of a particular column or set of columns.

InnoDB tables always have a clustered index representing the primary key. They can also have one or more secondary indexes defined on one or more columns. Depending on their structure, secondary indexes can be classified as partial, column, or composite indexes.

Indexes are a crucial aspect of query performance. Database architects design tables, queries, and indexes to allow fast lookups for data needed by applications. The ideal database design uses a covering index where practical; the query results are computed entirely from the index, without reading the actual table data. Each
foreign key constraint also requires an index, to efficiently check whether values exist in both the parent and child tables.

Although a B-tree index is the most common, a different kind of data structure is used for hash indexes, as in the MEMORY storage engine and the InnoDB adaptive hash index. R-tree indexes are used for spatial indexing of multi-dimensional information.

See Also adaptive hash index, B-tree, child table, clustered index, column index, composite index, covering index, foreign key, hash index, parent table, partial index, primary key, query, R-tree, row, secondary index, table.

index cache
A memory area that holds the token data for InnoDB full-text search. It buffers the data to minimize disk I/O when data is inserted or updated in columns that are part of a FULLTEXT index. The token data is written to disk when the index cache becomes full. Each InnoDB FULLTEXT index has its own separate index cache, whose size is controlled by the configuration option innodb_ft_cache_size.

See Also full-text search, FULLTEXT index.

index condition pushdown
Index condition pushdown (ICP) is an optimization that pushes part of a WHERE condition down to the storage engine if parts of the condition can be evaluated using fields from the index. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine. For more information, see Section 10.2.1.6, “Index Condition Pushdown Optimization”.

See Also index, storage engine.

index hint
Extended SQL syntax for overriding the indexes recommended by the optimizer. For example, the FORCE INDEX, USE INDEX, and IGNORE INDEX clauses. Typically used when indexed columns have unevenly distributed values, resulting in inaccurate cardinality estimates.

See Also cardinality, index.

index prefix
In an index that applies to multiple columns (known as a composite index), the initial or leading columns of the index. A query that references the first 1, 2, 3, and so on columns of a composite index can use the index, even if the query does not reference all the columns in the index.

See Also composite index, index.

index statistics
See statistics.

infimum record
A pseudo-record in an index, representing the gap below the smallest value in that index. If a transaction has a statement such as SELECT ... FROM ... WHERE col < 10 FOR UPDATE;, and the smallest value in the column is 5, it is a lock on the infimum record that prevents other transactions from inserting even smaller values such as 0, -10, and so on.

See Also gap, index, pseudo-record, supremum record.

INFORMATION_SCHEMA
The name of the database that provides a query interface to the MySQL data dictionary. (This name is defined by the ANSI SQL standard.) To examine information (metadata) about the database, you can query tables such as INFORMATION_SCHEMA.TABLES and INFORMATION_SCHEMA.COLUMNS, rather than using SHOW commands that produce unstructured output.

The INFORMATION_SCHEMA database also contains tables specific to InnoDB that provide a query interface to the InnoDB data dictionary. You use these tables not to see how the database is structured, but to get real-time information about the workings of InnoDB tables to help with performance monitoring, tuning, and troubleshooting.

See Also data dictionary, database, InnoDB.
InnoDB

A MySQL component that combines high performance with transactional capability for reliability, robustness, and concurrent access. It embodies the ACID design philosophy. Represented as a storage engine; it handles tables created or altered with the ENGINE=INNODB clause. See Chapter 17, The InnoDB Storage Engine for architectural details and administration procedures, and Section 10.5, “Optimizing for InnoDB Tables” for performance advice.

In MySQL 5.5 and higher, InnoDB is the default storage engine for new tables and the ENGINE=INNODB clause is not required.

InnoDB tables are ideally suited for hot backups. See Section 32.1, “MySQL Enterprise Backup Overview” for information about the MySQL Enterprise Backup product for backing up MySQL servers without interrupting normal processing.

See Also ACID, hot backup, MySQL Enterprise Backup, storage engine, transaction.

innodb_autoinc_lock_mode

The innodb_autoinc_lock_mode option controls the algorithm used for auto-increment locking. When you have an auto-incrementing primary key, you can use statement-based replication only with the setting innodb_autoinc_lock_mode=1. This setting is known as consecutive lock mode, because multi-row inserts within a transaction receive consecutive auto-increment values. If you have innodb_autoinc_lock_mode=2, which allows higher concurrency for insert operations, use row-based replication rather than statement-based replication. This setting is known as interleaved lock mode, because multiple multi-row insert statements running at the same time can receive auto-increment values that are interleaved. The setting innodb_autoinc_lock_mode=0 should not be used except for compatibility purposes.

Consecutive lock mode (innodb_autoinc_lock_mode=1) is the default setting prior to MySQL 8.0.3. As of MySQL 8.0.3, interleaved lock mode (innodb_autoinc_lock_mode=2) is the default, which reflects the change from statement-based to row-based replication as the default replication type.

See Also auto-increment, auto-increment locking, mixed-mode insert, primary key.

innodb_file_per_table

An important configuration option that affects many aspects of InnoDB file storage, availability of features, and I/O characteristics. In MySQL 5.6.7 and higher, it is enabled by default. The innodb_file_per_table option turns on file-per-table mode. With this mode enabled, a newly created InnoDB table and associated indexes can be stored in a file-per-table .ibd file, outside the system tablespace.

This option affects the performance and storage considerations for a number of SQL statements, such as DROP TABLE and TRUNCATE TABLE.

Enabling the innodb_file_per_table option allows you to take advantage of features such as table compression and named-table backups in MySQL Enterprise Backup.

For more information, see innodb_file_per_table, and Section 17.6.3.2, “File-Per-Table Tablespaces”. See Also compression, file-per-table, .ibd file, MySQL Enterprise Backup, system tablespace.

innodb_lock_wait_timeout

The innodb_lock_wait_timeout option sets the balance between waiting for shared resources to become available, or giving up and handling the error, retrying, or doing alternative processing in your application. Rolls back any InnoDB transaction that waits more than a specified time to acquire a lock. Especially useful if deadlocks are caused by updates to multiple tables controlled by different storage engines; such deadlocks are not detected automatically.

See Also deadlock, deadlock detection, lock, wait.

innodb_strict_mode

The innodb_strict_mode option controls whether InnoDB operates in strict mode, where conditions that are normally treated as warnings, cause errors instead (and the underlying statements fail).
See Also strict mode.

Innovation Series
Innovation releases with the same major version form an Innovation series. For example, MySQL 8.1 through 8.3 form the MySQL 8 Innovation series.
See Also LTS Series.

insert
One of the primary DML operations in SQL. The performance of inserts is a key factor in data warehouse systems that load millions of rows into tables, and OLTP systems where many concurrent connections might insert rows into the same table, in arbitrary order. If insert performance is important to you, you should learn about InnoDB features such as the insert buffer used in change buffering, and auto-increment columns.
See Also auto-increment, change buffering, data warehouse, DML, InnoDB, insert buffer, OLTP, SQL.

insert buffer
The former name of the change buffer. In MySQL 5.5, support was added for buffering changes to secondary index pages for DELETE and UPDATE operations. Previously, only changes resulting from INSERT operations were buffered. The preferred term is now change buffer.
See Also change buffer, change buffering.

insert buffering
The technique of storing changes to secondary index pages, resulting from INSERT operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. It is one of the types of change buffering; the others are delete buffering and purge buffering.

Insert buffering is not used if the secondary index is unique, because the uniqueness of new values cannot be verified before the new entries are written out. Other kinds of change buffering do work for unique indexes.
See Also change buffer, change buffering, delete buffering, insert buffer, purge buffering, unique index.

insert intention lock
A type of gap lock that is set by INSERT operations prior to row insertion. This type of lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. For more information, see Section 17.7.1, “InnoDB Locking”.
See Also gap lock, lock, next-key lock.

instance
A single mysqld daemon managing a data directory representing one or more databases with a set of tables. It is common in development, testing, and some replication scenarios to have multiple instances on the same server machine, each managing its own data directory and listening on its own port or socket. With one instance running a disk-bound workload, the server might still have extra CPU and memory capacity to run additional instances.
See Also data directory, database, disk-bound, mysqld, replication, server, table.

instrumentation
Modifications at the source code level to collect performance data for tuning and debugging. In MySQL, data collected by instrumentation is exposed through an SQL interface using the INFORMATION_SCHEMA and PERFORMANCE_SCHEMA databases.
See Also INFORMATION_SCHEMA, Performance Schema.

intention exclusive lock
See intention lock.

intention lock
A kind of lock that applies to the table, used to indicate the kind of lock the transaction intends to acquire on rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the
first transaction to acquire an *intention exclusive* (IX) lock on a table prevents other transactions from acquiring any S or X locks on the table. Conversely, the first transaction to acquire an *intention shared* (IS) lock on a table prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock requests to be resolved in order, without blocking locks and corresponding operations that are compatible. For more information about this locking mechanism, see Section 17.7.1, “InnoDB Locking”.

See Also lock, lock mode, locking, transaction.

intention shared lock
See intention lock.

interceptor
Code for instrumenting or debugging some aspect of an application, which can be enabled without recompiling or changing the source of the application itself.

See Also command interceptor, Connector/J, Connector/NET, exception interceptor.

intrinsic temporary table
An optimized internal InnoDB temporary table used by the optimizer.
See Also optimizer.

inverted index
A data structure optimized for document retrieval systems, used in the implementation of InnoDB full-text search. The InnoDB FULLTEXT index, implemented as an inverted index, records the position of each word within a document, rather than the location of a table row. A single column value (a document stored as a text string) is represented by many entries in the inverted index.
See Also full-text search, FULLTEXT index, ilist.

IOPS
Acronym for I/O operations per second. A common measurement for busy systems, particularly OLTP applications. If this value is near the maximum that the storage devices can handle, the application can become disk-bound, limiting scalability.
See Also disk-bound, OLTP, scalability.

isolation level
One of the foundations of database processing. Isolation is the I in the acronym ACID; the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

From highest amount of consistency and protection to the least, the isolation levels supported by InnoDB are: SERIALIZABLE, REPEATABLE READ, READ COMMITTED, and READ UNCOMMITTED.

With InnoDB tables, many users can keep the default isolation level (REPEATABLE READ) for all operations. Expert users might choose the READ COMMITTED level as they push the boundaries of scalability with OLTP processing, or during data warehousing operations where minor inconsistencies do not affect the aggregate results of large amounts of data. The levels on the edges (SERIALIZABLE and READ UNCOMMITTED) change the processing behavior to such an extent that they are rarely used.
See Also ACID, OLTP, READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, SERIALIZABLE, transaction.

J

J2EE
Java Platform, Enterprise Edition: Oracle's enterprise Java platform. It consists of an API and a runtime environment for enterprise-class Java applications. For full details, see http://www.oracle.com/technetwork/java/javasee/overview/index.html. With MySQL applications, you typically use Connector/J for database access, and
an application server such as **Tomcat** or **JBoss** to handle the middle-tier work, and optionally a framework such as **Spring**. Database-related features often offered within a J2EE stack include a **connection pool** and **failover** support.

See Also **connection pool**, **Connector/J**, **failover**, **Java**, **JBoss**, **Spring**, **Tomcat**.

**Java**

A programming language combining high performance, rich built-in features and data types, object-oriented mechanisms, extensive standard library, and wide range of reusable third-party modules. Enterprise development is supported by many frameworks, application servers, and other technologies. Much of its syntax is familiar to **C** and **C++** developers. To write Java applications with MySQL, you use the **JDBC** driver known as **Connector/J**.

See Also **C**, **Connector/J**, **C++**, **JDBC**.

**JBoss**

See Also **J2EE**.

**JDBC**

Abbreviation for “Java Database Connectivity”, an **API** for database access from **Java** applications. Java developers writing MySQL applications use the **Connector/J** component as their JDBC driver.

See Also **API**, **Connector/J**, **J2EE**, **Java**.

**JNDI**

See Also **Java**.

**join**

A **query** that retrieves data from more than one table, by referencing columns in the tables that hold identical values. Ideally, these columns are part of an **InnoDB** **foreign key** relationship, which ensures **referential integrity** and that the join columns are **indexed**. Often used to save space and improve query performance by replacing repeated strings with numeric IDs, in a **normalized** data design.

See Also **foreign key**, **index**, **normalized**, **query**, **referential integrity**.

**K**

**KDC**

See **key distribution center**.

**key distribution center**

In Kerberos, the key distribution center comprises an authentication server (AS) and a ticket-granting server (TGS).

See Also **authentication server**, **ticket-granting ticket**.

**keystore**

See Also **SSL**.

**KEY_BLOCK_SIZE**

An option to specify the size of data pages within an **InnoDB** table that uses **compressed row format**. The default is 8 kilobytes. Lower values risk hitting internal limits that depend on the combination of row size and compression percentage.

For **MyISAM** tables, **KEY_BLOCK_SIZE** optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A **KEY_BLOCK_SIZE** value specified for an individual index definition overrides a table-level **KEY_BLOCK_SIZE** value.
See Also compressed row format.

latch
A lightweight structure used by InnoDB to implement a lock for its own internal memory structures, typically held for a brief time measured in milliseconds or microseconds. A general term that includes both mutexes (for exclusive access) and rw-locks (for shared access). Certain latches are the focus of InnoDB performance tuning. Statistics about latch use and contention are available through the Performance Schema interface. See Also lock, locking, mutex, Performance Schema, rw-lock.

libmysql
Informal name for the libmysqlclient library. See Also libmysqlclient.

libmysqlclient
The library file, named libmysqlclient.a or libmysqlclient.so, that is typically linked into client programs written in C. Sometimes known informally as libmysql or the mysqlclient library. See Also client, libmysql, mysqlclient.

libmysqld
This embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications. You link with the libmysqld library rather than libmysqlclient. The API is identical between all three of these libraries. See Also client, embedded, libmysql, libmysqlclient.

lifecycle interceptor
A type of interceptor supported by Connector/J. It involves implementing the interface com.mysql.jdbc.ConnectionLifecycleInterceptor. See Also Connector/J, interceptor.

list
The InnoDB buffer pool is represented as a list of memory pages. The list is reordered as new pages are accessed and enter the buffer pool, as pages within the buffer pool are accessed again and are considered newer, and as pages that are not accessed for a long time are evicted from the buffer pool. The buffer pool is divided into sublists, and the replacement policy is a variation of the familiar LRU technique. See Also buffer pool, eviction, LRU, page, sublist.

load balancing
A technique for scaling read-only connections by sending query requests to different slave servers in a replication or Cluster configuration. With Connector/J, load balancing is enabled through the com.mysql.jdbc.ReplicationDriver class and controlled by the configuration property loadBalanceStrategy. See Also Connector/J, J2EE.

localhost
See Also connection.

lock
The high-level notion of an object that controls access to a resource, such as a table, row, or internal data structure, as part of a locking strategy. For intensive performance tuning, you might delve into the actual structures that implement locks, such as mutexes and latches.
See Also latch, lock mode, locking, mutex.

Lock escalation
An operation used in some database systems that converts many row locks into a single table lock, saving memory space but reducing concurrent access to the table. InnoDB uses a space-efficient representation for row locks, so that lock escalation is not needed.
See Also locking, row lock, table lock.

Lock mode
A shared (S) lock allows a transaction to read a row. Multiple transactions can acquire an S lock on that same row at the same time.

An exclusive (X) lock allows a transaction to update or delete a row. No other transaction can acquire any kind of lock on that same row at the same time.

Intention locks apply to the table, and are used to indicate what kind of lock the transaction intends to acquire on rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the first transaction to acquire an intention exclusive (IX) lock on a table prevents other transactions from acquiring any S or X locks on the table. Conversely, the first transaction to acquire an intention shared (IS) lock on a table prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock requests to be resolved in order, without blocking locks and corresponding operations that are compatible.
See Also intention lock, lock, locking, transaction.

Locking
The system of protecting a transaction from seeing or changing data that is being queried or changed by other transactions. The locking strategy must balance reliability and consistency of database operations (the principles of the ACID philosophy) against the performance needed for good concurrency. Fine-tuning the locking strategy often involves choosing an isolation level and ensuring all your database operations are safe and reliable for that isolation level.
See Also ACID, concurrency, isolation level, locking, transaction.

Locking read
A SELECT statement that also performs a locking operation on an InnoDB table. Either SELECT ... FOR UPDATE or SELECT ... LOCK IN SHARE MODE. It has the potential to produce a deadlock, depending on the isolation level of the transaction. The opposite of a non-locking read. Not allowed for global tables in a read-only transaction.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.

See Section 17.7.2.4, “Locking Reads”.
See Also deadlock, isolation level, locking, non-locking read, read-only transaction.

Log
In the InnoDB context, “log” or “log files” typically refers to the redo log represented by the ib_logfileN files. Another type of InnoDB log is the undo log, which is a storage area that holds copies of data modified by active transactions.

Other kinds of logs that are important in MySQL are the error log (for diagnosing startup and runtime problems), binary log (for working with replication and performing point-in-time restores), the general query log (for diagnosing application problems), and the slow query log (for diagnosing performance problems).
See Also binary log, error log, general query log, ib_logfile, redo log, slow query log, undo log.

Log buffer
The memory area that holds data to be written to the log files that make up the redo log. It is controlled by the innodb_log_buffer_size configuration option.
See Also log file, redo log.

log file

One of the *ib_logfile* files that make up the redo log. Data is written to these files from the log buffer memory area.

See Also ib_logfile, log buffer, redo log.

log group

The set of files that make up the redo log, typically named *ib_logfile0* and *ib_logfile1*. (For that reason, sometimes referred to collectively as *ib_logfile*.)

See Also ib_logfile, redo log.

logical

A type of operation that involves high-level, abstract aspects such as tables, queries, indexes, and other SQL concepts. Typically, logical aspects are important to make database administration and application development convenient and usable. Contrast with physical.

See Also logical backup, physical.

logical backup

A backup that reproduces table structure and data, without copying the actual data files. For example, the `mysqldump` command produces a logical backup, because its output contains statements such as `CREATE TABLE` and `INSERT` that can re-create the data. Contrast with physical backup. A logical backup offers flexibility (for example, you could edit table definitions or insert statements before restoring), but can take substantially longer to restore than a physical backup.

See Also backup, mysqldump, physical backup, restore.

loose

A prefix added to InnoDB configuration options after server startup, so any new configuration options not recognized by the current level of MySQL do not cause a startup failure. MySQL processes configuration options that start with this prefix, but gives a warning rather than a failure if the part after the prefix is not a recognized option.

See Also startup.

low-water mark

A value representing a lower limit, typically a threshold value at which some corrective action begins or becomes more aggressive. Contrast with high-water mark.

See Also high-water mark.

LRU

An acronym for “least recently used”, a common method for managing storage areas. The items that have not been used recently are evicted when space is needed to cache newer items. InnoDB uses the LRU mechanism by default to manage the pages within the buffer pool, but makes exceptions in cases where a page might be read only a single time, such as during a full table scan. This variation of the LRU algorithm is called the midpoint insertion strategy. For more information, see Section 17.5.1, “Buffer Pool”.

See Also buffer pool, eviction, full table scan, midpoint insertion strategy, page.

LSN

Acronym for “log sequence number”. This arbitrary, ever-increasing value represents a point in time corresponding to operations recorded in the redo log. (This point in time is regardless of transaction boundaries; it can fall in the middle of one or more transactions.) It is used internally by InnoDB during crash recovery and for managing the buffer pool.

Prior to MySQL 5.6.3, the LSN was a 4-byte unsigned integer. The LSN became an 8-byte unsigned integer in MySQL 5.6.3 when the redo log file size limit increased from 4GB to 512GB, as additional bytes were required to store extra size information. Applications built on MySQL 5.6.3 or later that use LSN values should use 64-bit rather than 32-bit variables to store and compare LSN values.
In the MySQL Enterprise Backup product, you can specify an LSN to represent the point in time from which to take an incremental backup. The relevant LSN is displayed by the output of the mysqlbackup command. Once you have the LSN corresponding to the time of a full backup, you can specify that value to take a subsequent incremental backup, whose output contains another LSN for the next incremental backup.

See Also buffer pool, crash recovery, incremental backup, MySQL Enterprise Backup, redo log, transaction.

LTS Series
LTS releases with the same major version number form an LTS series. For example, all MySQL 8.4.x releases form the MySQL 8.4 LTS series.

Note: MySQL 8.0 is a Bugfix series that preceded the LTS release model.

See Also Innovation Series.

M
.MRG file
A file containing references to other tables, used by the MERGE storage engine. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.
See Also MySQL Enterprise Backup, mysqlbackup command.

.MYD file
A file that MySQL uses to store data for a MyISAM table.
See Also .MYI file, MySQL Enterprise Backup, mysqlbackup command.

.MYI file
A file that MySQL uses to store indexes for a MyISAM table.
See Also .MYD file, MySQL Enterprise Backup, mysqlbackup command.

master
See source.

master thread
An InnoDB thread that performs various tasks in the background. Most of these tasks are I/O related, such as writing changes from the change buffer to the appropriate secondary indexes.

To improve concurrency, sometimes actions are moved from the master thread to separate background threads. For example, in MySQL 5.6 and higher, dirty pages are flushed from the buffer pool by the page cleaner thread rather than the master thread.
See Also buffer pool, change buffer, concurrency, dirty page, flush, page cleaner, thread.

MDL
Acronym for “metadata lock”.
See Also metadata lock.

medium trust
Synonym for partial trust. Because the range of trust settings is so broad, “partial trust” is preferred, to avoid the implication that there are only three levels (low, medium, and full).
See Also Connector/NET, partial trust.

memcached
A popular component of many MySQL and NoSQL software stacks, allowing fast reads and writes for single values and caching the results entirely in memory. Traditionally, applications required extra logic to write the same data to a MySQL database for permanent storage, or to read data from a MySQL database when it was not cached yet in memory. Now, applications can use the simple memcached protocol, supported by client libraries
for many languages, to communicate directly with MySQL servers using NDB tables. These NoSQL interfaces to MySQL tables allow applications to achieve higher read and write performance than by issuing SQL statements directly, and can simplify application logic and deployment configurations for systems that already incorporate memcached for in-memory caching.

See Also NoSQL.

merge
To apply changes to data cached in memory, such as when a page is brought into the buffer pool, and any applicable changes recorded in the change buffer are incorporated into the page in the buffer pool. The updated data is eventually written to the tablespace by the flush mechanism.

See Also buffer pool, change buffer, flush, tablespace.

metadata lock
A type of lock that prevents DDL operations on a table that is being used at the same time by another transaction. For details, see Section 10.11.4, “Metadata Locking”.

Enhancements to online operations, particularly in MySQL 5.6 and higher, are focused on reducing the amount of metadata locking. The objective is for DDL operations that do not change the table structure (such as CREATE INDEX and DROP INDEX for InnoDB tables) to proceed while the table is being queried, updated, and so on by other transactions.

See Also DDL, lock, online, transaction.

metrics counter
A feature implemented by the INNODB_METRICS table in the INFORMATION_SCHEMA, in MySQL 5.6 and higher. You can query counts and totals for low-level InnoDB operations, and use the results for performance tuning in combination with data from the Performance Schema.

See Also counter, INFORMATION_SCHEMA, Performance Schema.

midpoint insertion strategy
The technique of initially bringing pages into the InnoDB buffer pool not at the “newest” end of the list, but instead somewhere in the middle. The exact location of this point can vary, based on the setting of the innodb_old_blocks_pct option. The intent is that pages that are only read once, such as during a full table scan, can be aged out of the buffer pool sooner than with a strict LRU algorithm. For more information, see Section 17.5.1, “Buffer Pool”.

See Also buffer pool, full table scan, LRU, page.

mini-transaction
An internal phase of InnoDB processing, when making changes at the physical level to internal data structures during DML operations. A mini-transaction (mtr) has no notion of rollback; multiple mini-transactions can occur within a single transaction. Mini-transactions write information to the redo log that is used during crash recovery. A mini-transaction can also happen outside the context of a regular transaction, for example during purge processing by background threads.

See Also commit, crash recovery, DML, physical, purge, redo log, rollback, transaction.

mixed-mode insert
An INSERT statement where auto-increment values are specified for some but not all of the new rows. For example, a multi-value INSERT could specify a value for the auto-increment column in some cases and NULL in other cases. InnoDB generates auto-increment values for the rows where the column value was specified as NULL. Another example is an INSERT ... ON DUPLICATE KEY UPDATE statement, where auto-increment values might be generated but not used, for any duplicate rows that are processed as UPDATE rather than INSERT statements.

Can cause consistency issues between source and replica servers in a replication configuration. Can require adjusting the value of the innodb_autoinc_lock_mode configuration option.

See Also auto-increment, innodb_autoinc_lock_mode, replica, replication, source.
MM.MySQL
An older JDBC driver for MySQL that evolved into Connector/J when it was integrated with the MySQL product.
See Also Connector/J.

Mono
An Open Source framework developed by Novell, that works with Connector/NET and C# applications on Linux platforms.
See Also Connector/NET, C#.

mtr
See mini-transaction.

multi-core
A type of processor that can take advantage of multithreaded programs, such as the MySQL server.

multiversion concurrency control
See MVCC.

mutex
Informal abbreviation for “mutex variable”. (Mutex itself is short for “mutual exclusion”.) The low-level object that InnoDB uses to represent and enforce exclusive-access locks to internal in-memory data structures. Once the lock is acquired, any other process, thread, and so on is prevented from acquiring the same lock. Contrast with rw-locks, which InnoDB uses to represent and enforce shared-access locks to internal in-memory data structures. Mutexes and rw-locks are known collectively as latches.
See Also latch, lock, Performance Schema, Pthreads, rw-lock.

MVCC
Acronym for “multiversion concurrency control”. This technique lets InnoDB transactions with certain isolation levels perform consistent read operations; that is, to query rows that are being updated by other transactions, and see the values from before those updates occurred. This is a powerful technique to increase concurrency, by allowing queries to proceed without waiting due to locks held by the other transactions.
This technique is not universal in the database world. Some other database products, and some other MySQL storage engines, do not support it.
See Also ACID, concurrency, consistent read, isolation level, lock, transaction.

my.cnf
The name, on Unix or Linux systems, of the MySQL option file.
See Also my.ini, option file.

my.ini
The name, on Windows systems, of the MySQL option file.
See Also my.cnf, option file.

MyODBC drivers
Obsolete name for Connector/ODBC.
See Also Connector/ODBC.

mysql
The mysql program is the command-line interpreter for the MySQL database. It processes SQL statements, and also MySQL-specific commands such as SHOW TABLES, by passing requests to the mysqlld daemon.
See Also mysqlld, SQL.

MySQL Enterprise Backup
A licensed product that performs hot backups of MySQL databases. It offers the most efficiency and flexibility when backing up InnoDB tables, but can also back up MyISAM and other kinds of tables.
See Also hot backup, InnoDB.

mysqlbackup command
A command-line tool of the MySQL Enterprise Backup product. It performs a hot backup operation for InnoDB tables, and a warm backup for MyISAM and other kinds of tables. See Section 32.1, “MySQL Enterprise Backup Overview” for more information about this command.
See Also hot backup, MySQL Enterprise Backup, warm backup.

mysqlclient
The informal name for the library that is implemented by the file libmysqlclient, with extension .a or .so.
See Also libmysqlclient.

mysqld
mysqld, also known as MySQL Server, is a single multithreaded program that does most of the work in a MySQL installation. It does not spawn additional processes. MySQL Server manages access to the MySQL data directory that contains databases, tables, and other information such as log files and status files.
mysqld runs as a Unix daemon or Windows service, constantly waiting for requests and performing maintenance work in the background.
See Also instance, mysql.

MySQLdb
The name of the open-source Python module that forms the basis of the MySQL Python API.
See Also Python, Python API.

mysqldump
A command that performs a logical backup of some combination of databases, tables, and table data. The results are SQL statements that reproduce the original schema objects, data, or both. For substantial amounts of data, a physical backup solution such as MySQL Enterprise Backup is faster, particularly for the restore operation.
See Also logical backup, MySQL Enterprise Backup, physical backup, restore.

N

.NET
See Also ADO.NET, ASP.net, Connector/NET, Mono, Visual Studio.

native C API
Synonym for libmysqlclient.
See Also libmysql.

natural key
An indexed column, typically a primary key, where the values have some real-world significance. Usually advised against because:

- If the value should ever change, there is potentially a lot of index maintenance to re-sort the clustered index and update the copies of the primary key value that are repeated in each secondary index.

- Even seemingly stable values can change in unpredictable ways that are difficult to represent correctly in the database. For example, one country can change into two or several, making the original country code obsolete. Or, rules about unique values might have exceptions. For example, even if taxpayer IDs are intended to be unique to a single person, a database might have to handle records that violate that rule, such as in cases of identity theft. Taxpayer IDs and other sensitive ID numbers also make poor primary keys, because they may need to be secured, encrypted, and otherwise treated differently than other columns.
Thus, it is typically better to use arbitrary numeric values to form a **synthetic key**, for example using an **auto-increment** column.

See Also auto-increment, clustered index, primary key, secondary index, synthetic key.

**neighbor page**

Any **page** in the same **extent** as a particular page. When a page is selected to be **flushed**, any neighbor pages that are **dirty** are typically flushed as well, as an I/O optimization for traditional hard disks. In MySQL 5.6 and up, this behavior can be controlled by the configuration variable `innodb_flush_neighbors`; you might turn that setting off for SSD drives, which do not have the same overhead for writing smaller batches of data at random locations.

See Also dirty page, extent, flush, page.

**next-key lock**

A combination of a **record lock** on the index record and a **gap lock** on the gap before the index record.

See Also gap lock, locking, record lock.

**non-locking read**

A **query** that does not use the `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE` clauses. The only kind of query allowed for global tables in a **read-only transaction**. The opposite of a **locking read**. See Section 17.7.2.3, “Consistent Nonlocking Reads”.

`SELECT ... FOR SHARE` replaces `SELECT ... LOCK IN SHARE MODE` in MySQL 8.0.1, but `LOCK IN SHARE MODE` remains available for backward compatibility.

See Also locking read, query, read-only transaction.

**non-repeatable read**

The situation when a query retrieves data, and a later query within the same **transaction** retrieves what should be the same data, but the queries return different results (changed by another transaction committing in the meantime).

This kind of operation goes against the **ACID** principle of database design. Within a transaction, data should be consistent, with predictable and stable relationships.

Among different **isolation levels**, non-repeatable reads are prevented by the **serializable read** and **repeatable read** levels, and allowed by the **consistent read**, and **read uncommitted** levels.

See Also ACID, consistent read, isolation level, READ UNCOMMITTED, REPEATABLE READ, SERIALIZABLE, transaction.

**nonblocking I/O**

An industry term that means the same as **asynchronous I/O**.

See Also asynchronous I/O.

**normalized**

A database design strategy where data is split into multiple tables, and duplicate values condensed into single rows represented by an ID, to avoid storing, querying, and updating redundant or lengthy values. It is typically used in **OLTP** applications.

For example, an address might be given a unique ID, so that a census database could represent the relationship **lives at this address** by associating that ID with each member of a family, rather than storing multiple copies of a complex value such as **123 Main Street, Anytown, USA**.

For another example, although a simple address book application might store each phone number in the same table as a person's name and address, a phone company database might give each phone number a special ID, and store the numbers and IDs in a separate table. This normalized representation could simplify large-scale updates when area codes split apart.
Normalization is not always recommended. Data that is primarily queried, and only updated by deleting entirely and reloading, is often kept in fewer, larger tables with redundant copies of duplicate values. This data representation is referred to as **denormalized**, and is frequently found in data warehousing applications. See Also denormalized, foreign key, OLTP, relational.

**NoSQL**

A broad term for a set of data access technologies that do not use the SQL language as their primary mechanism for reading and writing data. Some NoSQL technologies act as key-value stores, only accepting single-value reads and writes; some relax the restrictions of the ACID methodology; still others do not require a pre-planned schema. MySQL users can combine NoSQL-style processing for speed and simplicity with SQL operations for flexibility and convenience, by using the **memcached** API to directly access some kinds of MySQL tables.

See Also ACID, memcached, schema, SQL.

**NOT NULL constraint**

A type of **constraint** that specifies that a **column** cannot contain any **NULL** values. It helps to preserve **referential integrity**, as the database server can identify data with erroneous missing values. It also helps in the arithmetic involved in query optimization, allowing the optimizer to predict the number of entries in an index on that column.

See Also column, constraint, NULL, primary key, referential integrity.

**NULL**

A special value in SQL, indicating the absence of data. Any arithmetic operation or equality test involving a **NULL** value, in turn produces a **NULL** result. (Thus it is similar to the IEEE floating-point concept of NaN, “not a number”.) Any aggregate calculation such as **AVG()** ignores rows with **NULL** values, when determining how many rows to divide by. The only test that works with **NULL** values uses the SQL idioms **IS NULL** or **IS NOT NULL**.

**NULL** values play a part in **index** operations, because for performance a database must minimize the overhead of keeping track of missing data values. Typically, **NULL** values are not stored in an index, because a query that tests an indexed column using a standard comparison operator could never match a row with a **NULL** value for that column. For the same reason, unique indexes do not prevent **NULL** values; those values simply are not represented in the index. Declaring a **NOT NULL** constraint on a column provides reassurance that there are no rows left out of the index, allowing for better query optimization (accurate counting of rows and estimation of whether to use the index).

Because the **primary key** must be able to uniquely identify every row in the table, a single-column primary key cannot contain any **NULL** values, and a multi-column primary key cannot contain any rows with **NULL** values in all columns.

Although the Oracle database allows a **NULL** value to be concatenated with a string, **InnoDB** treats the result of such an operation as **NULL**.

See Also index, primary key, SQL.

.OPT file

A file containing database configuration information. Files with this extension are included in backups produced by the **mysqlbackup** command of the MySQL Enterprise Backup product.

See Also MySQL Enterprise Backup, mysqlbackup command.

**ODBC**

Acronym for Open Database Connectivity, an industry-standard API. Typically used with Windows-based servers, or applications that require ODBC to communicate with MySQL. The MySQL ODBC driver is called **Connector/ODBC**.

See Also Connector/ODBC.
off-page column
A column containing variable-length data (such as BLOB and VARCHAR) that is too long to fit on a B-tree page. The data is stored in overflow pages. The DYNAMIC row format is more efficient for such storage than the older COMPACT row format.
See Also B-tree, compact row format, dynamic row format, overflow page.

OLTP
Acronym for “Online Transaction Processing”. A database system, or a database application, that runs a workload with many transactions, with frequent writes as well as reads, typically affecting small amounts of data at a time. For example, an airline reservation system or an application that processes bank deposits. The data might be organized in normalized form for a balance between DML (insert/update/delete) efficiency and query efficiency. Contrast with data warehouse.
With its row-level locking and transactional capability, InnoDB is the ideal storage engine for MySQL tables used in OLTP applications.
See Also data warehouse, DML, InnoDB, query, row lock, transaction.

online
A type of operation that involves no downtime, blocking, or restricted operation for the database. Typically applied to DDL. Operations that shorten the periods of restricted operation, such as fast index creation, have evolved into a wider set of online DDL operations in MySQL 5.6.
In the context of backups, a hot backup is an online operation and a warm backup is partially an online operation.
See Also DDL, Fast Index Creation, hot backup, online DDL, warm backup.

online DDL
A feature that improves the performance, concurrency, and availability of InnoDB tables during DDL (primarily ALTER TABLE) operations. See Section 17.12, “InnoDB and Online DDL” for details.
The details vary according to the type of operation. In some cases, the table can be modified concurrently while the ALTER TABLE is in progress. The operation might be able to be performed without a table copy, or using a specially optimized type of table copy. DML log space usage for in-place operations is controlled by the innodb_online_alter_log_max_size configuration option.
This feature is an enhancement of the Fast Index Creation feature in MySQL 5.5.
See Also DDL, Fast Index Creation, online.

optimistic
A methodology that guides low-level implementation decisions for a relational database system. The requirements of performance and concurrency in a relational database mean that operations must be started or dispatched quickly. The requirements of consistency and referential integrity mean that any operation could fail: a transaction might be rolled back, a DML operation could violate a constraint, a request for a lock could cause a deadlock, a network error could cause a timeout. An optimistic strategy is one that assumes most requests or attempts succeed, so that relatively little work is done to prepare for the failure case. When this assumption is true, the database does little unnecessary work; when requests do fail, extra work must be done to clean up and undo changes.

InnoDB uses optimistic strategies for operations such as locking and commits. For example, data changed by a transaction can be written to the data files before the commit occurs, making the commit itself very fast, but requiring more work to undo the changes if the transaction is rolled back.
The opposite of an optimistic strategy is a pessimistic one, where a system is optimized to deal with operations that are unreliable and frequently unsuccessful. This methodology is rare in a database system, because so much care goes into choosing reliable hardware, networks, and algorithms.
See Also commit, concurrency, DML, locking, pessimistic, referential integrity.

**optimizer**

The MySQL component that determines the best indexes and join order to use for a query, based on characteristics and data distribution of the relevant tables.

See Also index, join, query, table.

**option**

A configuration parameter for MySQL, either stored in the option file or passed on the command line.

For the options that apply to InnoDB tables, each option name starts with the prefix innodb_.

See Also InnoDB, option, option file.

**option file**

The file that holds the configuration options for the MySQL instance. Traditionally, on Linux and Unix this file is named my.cnf, and on Windows it is named my.ini.

See Also configuration file, my.cnf, my.ini, option.

**overflow page**

Separately allocated disk pages that hold variable-length columns (such as BLOB and VARCHAR) that are too long to fit on a B-tree page. The associated columns are known as off-page columns.

See Also B-tree, off-page column, page.

**.par file**

A file containing partition definitions. Files with this extension are included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.

With the introduction of native partitioning support for InnoDB tables in MySQL 5.7.6, .par files are no longer created for partitioned InnoDB tables. Partitioned MyISAM tables continue to use .par files in MySQL 5.7. In MySQL 8.0, partitioning support is only provided by the InnoDB storage engine. As such, .par files are no longer used as of MySQL 8.0.

See Also MySQL Enterprise Backup, mysqlbackup command.

**page**

A unit representing how much data InnoDB transfers at any one time between disk (the data files) and memory (the buffer pool). A page can contain one or more rows, depending on how much data is in each row. If a row does not fit entirely into a single page, InnoDB sets up additional pointer-style data structures so that the information about the row can be stored in one page.

One way to fit more data in each page is to use compressed row format. For tables that use BLOBs or large text fields, compact row format allows those large columns to be stored separately from the rest of the row, reducing I/O overhead and memory usage for queries that do not reference those columns.

When InnoDB reads or writes sets of pages as a batch to increase I/O throughput, it reads or writes an extent at a time.

All the InnoDB disk data structures within a MySQL instance share the same page size.

See Also buffer pool, compact row format, compressed row format, data files, extent, page size, row.

**page cleaner**

An InnoDB background thread that flushes dirty pages from the buffer pool. Prior to MySQL 5.6, this activity was performed by the master thread. The number of page cleaner threads is controlled by the innodb_page_cleaners configuration option, introduced in MySQL 5.7.4.
See Also buffer pool, dirty page, flush, master thread, thread.

page size
For releases up to and including MySQL 5.5, the size of each InnoDB page is fixed at 16 kilobytes. This value represents a balance: large enough to hold the data for most rows, yet small enough to minimize the performance overhead of transferring unneeded data to memory. Other values are not tested or supported.

Starting in MySQL 5.6, the page size for an InnoDB instance can be either 4KB, 8KB, or 16KB, controlled by the innodb_page_size configuration option. As of MySQL 5.7.6, InnoDB also supports 32KB and 64KB page sizes. For 32KB and 64KB page sizes, ROW_FORMAT=COMPRESSED is not supported and the maximum record size is 16KB.

Page size is set when creating the MySQL instance, and it remains constant afterward. The same page size applies to all InnoDB tablespaces, including the system tablespace, file-per-table tablespaces, and general tablespaces.

Smaller page sizes can help performance with storage devices that use small block sizes, particularly for SSD devices in disk-bound workloads, such as for OLTP applications. As individual rows are updated, less data is copied into memory, written to disk, reorganized, locked, and so on.

See Also disk-bound, file-per-table, general tablespace, instance, OLTP, page, SSD, system tablespace, tablespace.

parent table
The table in a foreign key relationship that holds the initial column values pointed to from the child table. The consequences of deleting, or updating rows in the parent table depend on the ON UPDATE and ON DELETE clauses in the foreign key definition. Rows with corresponding values in the child table could be automatically deleted or updated in turn, or those columns could be set to NULL, or the operation could be prevented.

See Also child table, foreign key.

partial backup
A backup that contains some of the tables in a MySQL database, or some of the databases in a MySQL instance. Contrast with full backup.

See Also backup, full backup, table.

partial index
An index that represents only part of a column value, typically the first N characters (the prefix) of a long VARCHAR value.

See Also index, index prefix.

partial trust
An execution environment typically used by hosting providers, where applications have some permissions but not others. For example, applications might be able to access a database server over a network, but be “sandboxed” with regard to reading and writing local files.

See Also Connector/NET.

Performance Schema
The performance_schema schema, in MySQL 5.5 and up, presents a set of tables that you can query to get detailed information about the performance characteristics of many internal parts of the MySQL server. See Chapter 29, MySQL Performance Schema.

See Also INFORMATION_SCHEMA, latch, mutex, rw-lock.

Perl
A programming language with roots in Unix scripting and report generation. Incorporates high-performance regular expressions and file I/O. Large collection of reusable modules available through repositories such as CPAN.

See Also Perl API.
Perl API
An open-source API for MySQL applications written in the Perl language. Implemented through the DBI and DBD::mysql modules. For details, see Section 31.9, “MySQL Perl API”.
See Also API, Perl.

persistent statistics
A feature that stores index statistics for InnoDB tables on disk, providing better plan stability for queries. For more information, see Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.
See Also index, optimizer, plan stability, query, table.

pessimistic
A methodology that sacrifices performance or concurrency in favor of safety. It is appropriate if a high proportion of requests or attempts might fail, or if the consequences of a failed request are severe. InnoDB uses what is known as a pessimistic locking strategy, to minimize the chance of deadlocks. At the application level, you might avoid deadlocks by using a pessimistic strategy of acquiring all locks needed by a transaction at the very beginning.

Many built-in database mechanisms use the opposite optimistic methodology.
See Also deadlock, locking, optimistic.

phantom
A row that appears in the result set of a query, but not in the result set of an earlier query. For example, if a query is run twice within a transaction, and in the meantime, another transaction commits after inserting a new row or updating a row so that it matches the WHERE clause of the query.

This occurrence is known as a phantom read. It is harder to guard against than a non-repeatable read, because locking all the rows from the first query result set does not prevent the changes that cause the phantom to appear.

Among different isolation levels, phantom reads are prevented by the serializable read level, and allowed by the repeatable read, consistent read, and read uncommitted levels.
See Also consistent read, isolation level, non-repeatable read, READ UNCOMMITTED, REPEATABLE READ, SERIALIZABLE, transaction.

PHP
A programming language originating with web applications. The code is typically embedded as blocks within the source of a web page, with the output substituted into the page as it is transmitted by the web server. This is in contrast to applications such as CGI scripts that print output in the form of an entire web page. The PHP style of coding is used for highly interactive and dynamic web pages. Modern PHP programs can also be run as command-line or GUI applications.

MySQL applications are written using one of the PHP APIs. Reusable modules can be written in C and called from PHP.

Another technology for writing server-side web pages with MySQL is ASP.net.
See Also ASP.net, C, PHP API.

PHP API
Several APIs are available for writing MySQL applications in the PHP language: the original MySQL API (Mysql) the MySQL Improved Extension (Mysqli) the MySQL Native Driver (Mysqlnd) the MySQL functions (PDO_MYSQL), and Connector/PHP. For details, see MySQL and PHP.
See Also API, PHP.

physical
A type of operation that involves hardware-related aspects such as disk blocks, memory pages, files, bits, disk reads, and so on. Typically, physical aspects are important during expert-level performance tuning and problem diagnosis. Contrast with logical.
physical backup

A backup that copies the actual data files. For example, the `mysqlbackup` command of the MySQL Enterprise Backup product produces a physical backup, because its output contains data files that can be used directly by the `mysqld` server, resulting in a faster restore operation. Contrast with logical backup.

See Also backup, logical backup, MySQL Enterprise Backup, restore.

PITR

Acronym for point-in-time recovery.

See Also point-in-time recovery.

plan stability

A property of a query execution plan, where the optimizer makes the same choices each time for a given query, so that performance is consistent and predictable.

See Also query, query execution plan.

point-in-time recovery

The process of restoring a backup to recreate the state of the database at a specific date and time. Commonly abbreviated "PITR". Because it is unlikely that the specified time corresponds exactly to the time of a backup, this technique usually requires a combination of a physical backup and a logical backup. For example, with the MySQL Enterprise Backup product, you restore the last backup that you took before the specified point in time, then replay changes from the binary log between the time of the backup and the PITR time.

See Also backup, binary log, logical backup, MySQL Enterprise Backup, physical backup.

port

The number of the TCP/IP socket the database server listens on, used to establish a connection. Often specified in conjunction with a host. Depending on your use of network encryption, there might be one port for unencrypted traffic and another port for SSL connections.

See Also connection, host, SSL.

prefix

See index prefix.

prepared backup

A set of backup files, produced by the MySQL Enterprise Backup product, after all the stages of applying binary logs and incremental backups are finished. The resulting files are ready to be restored. Prior to the apply steps, the files are known as a raw backup.

See Also binary log, hot backup, incremental backup, MySQL Enterprise Backup, raw backup, restore.

prepared statement

An SQL statement that is analyzed in advance to determine an efficient execution plan. It can be executed multiple times, without the overhead for parsing and analysis each time. Different values can be substituted for literals in the WHERE clause each time, through the use of placeholders. This substitution technique improves security, protecting against some kinds of SQL injection attacks. You can also reduce the overhead for converting and copying return values to program variables.

Although you can use prepared statements directly through SQL syntax, the various Connectors have programming interfaces for manipulating prepared statements, and these APIs are more efficient than going through SQL.

See Also client-side prepared statement, connector, server-side prepared statement.

primary key

A set of columns—and by implication, the index based on this set of columns—that can uniquely identify every row in a table. As such, it must be a unique index that does not contain any NULL values.
**InnoDB** requires that every table has such an index (also called the **clustered index** or **cluster index**), and organizes the table storage based on the column values of the primary key.

When choosing primary key values, consider using arbitrary values (a **synthetic key**) rather than relying on values derived from some other source (a **natural key**).

**See Also** clustered index, index, natural key, synthetic key.

**principal**

The Kerberos term for a named entity, such as a user or server.

**See Also** service principal name, user principal name.

**process**

An instance of an executing program. The operating system switches between multiple running processes, allowing for a certain degree of **concurrency**. On most operating systems, processes can contain multiple **threads** of execution that share resources. Context-switching between threads is faster than the equivalent switching between processes.

**See Also** concurrency, thread.

**pseudo-record**

An artificial record in an index, used for **locking** key values or ranges that do not currently exist.

**See Also** infimum record, locking, supremum record.

**Pthreads**

The POSIX threads standard, which defines an API for threading and locking operations on Unix and Linux systems. On Unix and Linux systems, **InnoDB** uses this implementation for **mutexes**.

**See Also** mutex.

**purge**

A type of garbage collection performed by one or more separate background threads (controlled by `innodb_purge_threads`) that runs on a periodic schedule. Purge parses and processes **undo log** pages from the **history list** for the purpose of removing clustered and secondary index records that were marked for deletion (by previous **DELETE** statements) and are no longer required for **MVCC** or **rollback**. Purge frees undo log pages from the history list after processing them.

**See Also** history list, MVCC, rollback, undo log.

**purge buffering**

The technique of storing changes to secondary index pages, resulting from **DELETE** operations, in the **change buffer** rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally purges an index record that was previously marked for deletion.) It is one of the types of **change buffering**; the others are **insert buffering** and **delete buffering**.

**See Also** change buffer, change buffering, delete buffering, insert buffer, insert buffering.

**purge lag**

Another name for the **InnoDB history list**. Related to the `innodb_max_purge_lag` configuration option.

**See Also** history list, purge.

**purge thread**

A **thread** within the **InnoDB** process that is dedicated to performing the periodic **purge** operation. In MySQL 5.6 and higher, multiple purge threads are enabled by the `innodb_purge_threads` configuration option.

**See Also** purge, thread.

**Python**

A programming language used in a broad range of fields, from Unix scripting to large-scale applications. Includes runtime typing, built-in high-level data types, object-oriented features, and an extensive standard library. Often
used as a “glue” language between components written in other languages. The MySQL Python API is the open-source MySQLdb module.
See Also MySQLdb, Python API.

Python API

See Also API, Python.

Q

query

In SQL, an operation that reads information from one or more tables. Depending on the organization of data and the parameters of the query, the lookup might be optimized by consulting an index. If multiple tables are involved, the query is known as a join.

For historical reasons, sometimes discussions of internal processing for statements use “query” in a broader sense, including other types of MySQL statements such as DDL and DML statements.
See Also DDL, DML, index, join, SQL, table.

query execution plan

The set of decisions made by the optimizer about how to perform a query most efficiently, including which index or indexes to use, and the order in which to join tables. Plan stability involves the same choices being made consistently for a given query.
See Also index, join, plan stability, query.

query log

See general query log.

quiesce

To reduce the amount of database activity, often in preparation for an operation such as an ALTER TABLE, a backup, or a shutdown. Might or might not involve doing as much flushing as possible, so that InnoDB does not continue doing background I/O.

In MySQL 5.6 and higher, the syntax FLUSH TABLES ... FOR EXPORT writes some data to disk for InnoDB tables that make it simpler to back up those tables by copying the data files.
See Also backup, flush, InnoDB, shutdown.

R

R-tree

A tree data structure used for spatial indexing of multi-dimensional data such as geographical coordinates, rectangles or polygons.
See Also B-tree.

RAID

Acronym for “Redundant Array of Inexpensive Drives”. Spreading I/O operations across multiple drives enables greater concurrency at the hardware level, and improves the efficiency of low-level write operations that otherwise would be performed in sequence.
See Also concurrency.

random dive

A technique for quickly estimating the number of different values in a column (the column's cardinality). InnoDB samples pages at random from the index and uses that data to estimate the number of different values.
See Also cardinality.
The initial set of backup files produced by the MySQL Enterprise Backup product, before the changes reflected in the binary log and any incremental backups are applied. At this stage, the files are not ready to restore. After these changes are applied, the files are known as a prepared backup.

See Also: binary log, hot backup, ibbackup_logfile, incremental backup, MySQL Enterprise Backup, prepared backup, restore.

**READ COMMITTED**

An isolation level that uses a locking strategy that relaxes some of the protection between transactions, in the interest of performance. Transactions cannot see uncommitted data from other transactions, but they can see data that is committed by another transaction after the current transaction started. Thus, a transaction never sees any bad data, but the data that it does see may depend to some extent on the timing of other transactions.

When a transaction with this isolation level performs UPDATE ... WHERE or DELETE ... WHERE operations, other transactions might have to wait. The transaction can perform SELECT ... FOR UPDATE, and LOCK IN SHARE MODE operations without making other transactions wait.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.

See Also: ACID, isolation level, locking, REPEATABLE READ, SERIALIZABLE, transaction.

**read phenomena**

Phenomena such as dirty reads, non-repeatable reads, and phantom reads which can occur when a transaction reads data that another transaction has modified.

See Also: dirty read, non-repeatable read, phantom.

**READ UNCOMMITTED**

The isolation level that provides the least amount of protection between transactions. Queries employ a locking strategy that allows them to proceed in situations where they would normally wait for another transaction. However, this extra performance comes at the cost of less reliable results, including data that has been changed by other transactions and not committed yet (known as dirty read). Use this isolation level with great caution, and be aware that the results might not be consistent or reproducible, depending on what other transactions are doing at the same time. Typically, transactions with this isolation level only do queries, not insert, update, or delete operations.

See Also: ACID, dirty read, isolation level, locking, transaction.

**read view**

An internal snapshot used by the MVCC mechanism of InnoDB. Certain transactions, depending on their isolation level, see the data values as they were at the time the transaction (or in some cases, the statement) started. Isolation levels that use a read view are REPEATABLE READ, READ COMMITTED, and READ UNCOMMITTED.

See Also: isolation level, MVCC, READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, transaction.

**read-ahead**

A type of I/O request that prefetches a group of pages (an entire extent) into the buffer pool asynchronously, in case these pages are needed soon. The linear read-ahead technique prefetches all the pages of one extent based on access patterns for pages in the preceding extent. The random read-ahead technique prefetches all the pages for an extent once a certain number of pages from the same extent are in the buffer pool. Random read-ahead is not part of MySQL 5.5, but is re-introduced in MySQL 5.6 under the control of the innodb_random_read_ahead configuration option.

See Also: buffer pool, extent, page.

**read-only transaction**

A type of transaction that can be optimized for InnoDB tables by eliminating some of the bookkeeping involved with creating a read view for each transaction. Can only perform non-locking read queries. It can be started...
explicitly with the syntax `START TRANSACTION READ ONLY`, or automatically under certain conditions. See Section 10.5.3, “Optimizing InnoDB Read-Only Transactions” for details. See Also non-locking read, read view, transaction.

**record lock**
A lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10. Contrast with gap lock and next-key lock.
See Also gap lock, lock, next-key lock.

**redo**
The data, in units of records, recorded in the redo log when DML statements make changes to InnoDB tables. It is used during crash recovery to correct data written by incomplete transactions. The ever-increasing LSN value represents the cumulative amount of redo data that has passed through the redo log.
See Also crash recovery, DML, LSN, redo log, transaction.

**redo log**
A disk-based data structure used during crash recovery, to correct data written by incomplete transactions. During normal operation, it encodes requests to change InnoDB table data, which result from SQL statements or low-level API calls. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically.

The redo log is physically represented on disk as a set of redo log files. Redo log data is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo log is represented by an ever-increasing LSN value.

For more information, see Section 17.6.5, “Redo Log”
See Also crash recovery, data files, ib_logfile, log buffer, LSN, redo, shutdown, transaction.

**redo log archiving**
An InnoDB feature that, when enabled, sequentially writes redo log records to an archive file to avoid potential loss of data than can occur when a backup utility fails to keep pace with redo log generation while a backup operation is in progress. For more information, see Redo Log Archiving.
See Also redo log.

**redundant row format**
The oldest InnoDB row format. Prior to MySQL 5.0.3, it was the only row format available in InnoDB. From MySQL 5.0.3 to MySQL 5.7.8, the default row format is COMPACT. As of MySQL 5.7.9, the default row format is defined by the `innodb_default_row_format` configuration option, which has a default setting of DYNAMIC. You can still specify the REDUNDANT row format for compatibility with older InnoDB tables.

For more information, see Section 17.10, “InnoDB Row Formats”.
See Also compact row format, dynamic row format, row format.

**referential integrity**
The technique of maintaining data always in a consistent format, part of the ACID philosophy. In particular, data in different tables is kept consistent through the use of foreign key constraints, which can prevent changes from happening or automatically propagate those changes to all related tables. Related mechanisms include the unique constraint, which prevents duplicate values from being inserted by mistake, and the NOT NULL constraint, which prevents blank values from being inserted by mistake.
See Also ACID, FOREIGN KEY constraint, NOT NULL constraint, unique constraint.

**relational**
An important aspect of modern database systems. The database server encodes and enforces relationships such as one-to-one, one-to-many, many-to-one, and uniqueness. For example, a person might have zero, one, or many phone numbers in an address database; a single phone number might be associated with several family
members. In a financial database, a person might be required to have exactly one taxpayer ID, and any taxpayer ID could only be associated with one person.

The database server can use these relationships to prevent bad data from being inserted, and to find efficient ways to look up information. For example, if a value is declared to be unique, the server can stop searching as soon as the first match is found, and it can reject attempts to insert a second copy of the same value.

At the database level, these relationships are expressed through SQL features such as columns within a table, unique and NOT NULL constraints, foreign keys, and different kinds of join operations. Complex relationships typically involve data split between more than one table. Often, the data is normalized, so that duplicate values in one-to-many relationships are stored only once.

In a mathematical context, the relations within a database are derived from set theory. For example, the OR and AND operators of a WHERE clause represent the notions of union and intersection.

See Also ACID, column, constraint, foreign key, normalized.

relevance

In the full-text search feature, a number signifying the similarity between the search string and the data in the FULLTEXT index. For example, when you search for a single word, that word is typically more relevant for a row where it occurs several times in the text than a row where it appears only once.

See Also full-text search, FULLTEXT index.

REPEATABLE READ

The default isolation level for InnoDB. It prevents any rows that are queried from being changed by other transactions, thus blocking non-repeatable reads but not phantom reads. It uses a moderately strict locking strategy so that all queries within a transaction see data from the same snapshot, that is, the data as it was at the time the transaction started.

When a transaction with this isolation level performs UPDATE ... WHERE, DELETE ... WHERE, SELECT ..., FOR UPDATE, and LOCK IN SHARE MODE operations, other transactions might have to wait.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.

See Also ACID, consistent read, isolation level, locking, phantom, transaction.

repertoire

Repertoire is a term applied to character sets. A character set repertoire is the collection of characters in the set.

See Section 12.2.1, "Character Set Repertoire".

replica

A database server machine in a replication topology that receives changes from another server (the source) and applies those same changes. Thus it maintains the same contents as the source, although it might lag somewhat behind.

In MySQL, replicas are commonly used in disaster recovery, to take the place of a source that fails. They are also commonly used for testing software upgrades and new settings, to ensure that database configuration changes do not cause problems with performance or reliability.

Replicas typically have high workloads, because they process all the DML (write) operations relayed from the source, as well as user queries. To ensure that replicas can apply changes from the source fast enough, they frequently have fast I/O devices and sufficient CPU and memory to run multiple database instances on the same server. For example, the source might use hard drive storage while the replicas use SSDs.

See Also DML, replication, server, source, SSD.

replication

The practice of sending changes from a source, to one or more replicas, so that all databases have the same data. This technique has a wide range of uses, such as load-balancing for better scalability, disaster recovery,
and testing software upgrades and configuration changes. The changes can be sent between the databases by methods called row-based replication and statement-based replication.
See Also replica, row-based replication, source, statement-based replication.

restore
The process of putting a set of backup files from the MySQL Enterprise Backup product in place for use by MySQL. This operation can be performed to fix a corrupted database, to return to some earlier point in time, or (in a replication context) to set up a new replica. In the MySQL Enterprise Backup product, this operation is performed by the copy-back option of the mysqlbackup command.
See Also hot backup, MySQL Enterprise Backup, mysqlbackup command, prepared backup, replica, replication.

rollback
A SQL statement that ends a transaction, undoing any changes made by the transaction. It is the opposite of commit, which makes permanent any changes made in the transaction.
By default, MySQL uses the autocommit setting, which automatically issues a commit following each SQL statement. You must change this setting before you can use the rollback technique.
See Also ACID, autocommit, commit, SQL, transaction.

rollback segment
The storage area containing the undo logs. Rollback segments have traditionally resided in the system tablespace. As of MySQL 5.6, rollback segments can reside in undo tablespaces. As of MySQL 5.7, rollback segments are also allocated to the global temporary tablespace.
See Also global temporary tablespace, system tablespace, undo log, undo tablespace.

row
The logical data structure defined by a set of columns. A set of rows makes up a table. Within InnoDB data files, each page can contain one or more rows.
Although InnoDB uses the term row format for consistency with MySQL syntax, the row format is a property of each table and applies to all rows in that table.
See Also column, data files, page, row format, table.

row format
The disk storage format for rows of an InnoDB table. As InnoDB gains new capabilities such as compression, new row formats are introduced to support the resulting improvements in storage efficiency and performance.
The row format of an InnoDB table is specified by the ROW_FORMAT option or by the innodb_default_row_format configuration option (introduced in MySQL 5.7.9). Row formats include REDUNDANT, COMPACT, COMPRESSED, and DYNAMIC. To view the row format of an InnoDB table, issue the SHOW TABLE STATUS statement or query InnoDB table metadata in the INFORMATION_SCHEMA.
See Also compact row format, compressed row format, compression, dynamic row format, redundant row format, row, table.

row lock
A lock that prevents a row from being accessed in an incompatible way by another transaction. Other rows in the same table can be freely written to by other transactions. This is the type of locking done by DML operations on InnoDB tables.
Contrast with table locks used by MyISAM, or during DDL operations on InnoDB tables that cannot be done with online DDL; those locks block concurrent access to the table.
See Also DDL, DML, InnoDB, lock, locking, online DDL, table lock, transaction.

row-based replication
A form of replication where events are propagated from the source specifying how to change individual rows on the replica. It is safe to use for all settings of the innodb_autoinc_lock_mode option.
row-level locking

The locking mechanism used for InnoDB tables, relying on **row locks** rather than **table locks**. Multiple transactions can modify the same table concurrently. Only if two transactions try to modify the same row does one of the transactions wait for the other to complete (and release its row locks).

See Also InnoDB, locking, row lock, table lock, transaction.

Ruby

A programming language that emphasizes dynamic typing and object-oriented programming. Some syntax is familiar to Perl developers.

See Also API, Perl, Ruby API.

Ruby API

mysql2, based on the libmysqlclient API library, is available for Ruby programmers developing MySQL applications. For more information, see Section 31.11, “MySQL Ruby APIs”.

See Also libmysql, Ruby.

rw-lock

The low-level object that InnoDB uses to represent and enforce shared-access locks to internal in-memory data structures following certain rules. Contrast with mutexes, which InnoDB uses to represent and enforce exclusive access to internal in-memory data structures. Mutexes and rw-locks are known collectively as latches.

**rw-lock** types include **s-locks** (shared locks), **x-locks** (exclusive locks), and **sx-locks** (shared-exclusive locks).

- An **s-lock** provides read access to a common resource.
- An **x-lock** provides write access to a common resource while not permitting inconsistent reads by other threads.
- An **sx-lock** provides write access to a common resource while permitting inconsistent reads by other threads. **sx-locks** were introduced in MySQL 5.7 to optimize concurrency and improve scalability for read-write workloads.

The following matrix summarizes rw-lock type compatibility.

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>SX</th>
<th>X</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Conflict</td>
</tr>
<tr>
<td>SX</td>
<td>Compatible</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
<tr>
<td>X</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
</tbody>
</table>

See Also latch, lock, mutex, Performance Schema.

S

savepoint

Savepoints help to implement nested transactions. They can be used to provide scope to operations on tables that are part of a larger transaction. For example, scheduling a trip in a reservation system might involve booking several different flights; if a desired flight is unavailable, you might roll back the changes involved in booking that one leg, without rolling back the earlier flights that were successfully booked.
 scalability

The ability to add more work and issue more simultaneous requests to a system, without a sudden drop in performance due to exceeding the limits of system capacity. Software architecture, hardware configuration, application coding, and type of workload all play a part in scalability. When the system reaches its maximum capacity, popular techniques for increasing scalability are scale up (increasing the capacity of existing hardware or software) and scale out (adding new servers and more instances of MySQL). Often paired with availability as critical aspects of a large-scale deployment.

See Also availability, scale out, scale up.

scale out

A technique for increasing scalability by adding new servers and more instances of MySQL. For example, setting up replication, NDB Cluster, connection pooling, or other features that spread work across a group of servers. Contrast with scale up.

See Also scalability, scale up.

scale up

A technique for increasing scalability by increasing the capacity of existing hardware or software. For example, increasing the memory on a server and adjusting memory-related parameters such as innodb_buffer_pool_size and innodb_buffer_pool_instances. Contrast with scale out.

See Also scalability, scale out.

schema

Conceptually, a schema is a set of interrelated database objects, such as tables, table columns, data types of the columns, indexes, foreign keys, and so on. These objects are connected through SQL syntax, because the columns make up the tables, the foreign keys refer to tables and columns, and so on. Ideally, they are also connected logically, working together as part of a unified application or flexible framework. For example, the INFORMATION_SCHEMA and performance_schema databases use “schema” in their names to emphasize the close relationships between the tables and columns they contain.

In MySQL, physically, a schema is synonymous with a database. You can substitute the keyword SCHEMA instead of DATABASE in MySQL SQL syntax, for example using CREATE SCHEMA instead of CREATE DATABASE.

Some other database products draw a distinction. For example, in the Oracle Database product, a schema represents only a part of a database: the tables and other objects owned by a single user.

See Also database, INFORMATION_SCHEMA, Performance Schema.

SDI

Acronym for “serialized dictionary information”.

See Also serialized dictionary information (SDI).

search index

In MySQL, full-text search queries use a special kind of index, the FULLTEXT index. In MySQL 5.6.4 and up, InnoDB and MyISAM tables both support FULLTEXT indexes; formerly, these indexes were only available for MyISAM tables.

See Also full-text search, FULLTEXT index.

secondary index

A type of InnoDB index that represents a subset of table columns. An InnoDB table can have zero, one, or many secondary indexes. (Contrast with the clustered index, which is required for each InnoDB table, and stores the data for all the table columns.)

A secondary index can be used to satisfy queries that only require values from the indexed columns. For more complex queries, it can be used to identify the relevant rows in the table, which are then retrieved through lookups using the clustered index.
Creating and dropping secondary indexes has traditionally involved significant overhead from copying all the data in the InnoDB table. The fast index creation feature makes both `CREATE INDEX` and `DROP INDEX` statements much faster for InnoDB secondary indexes.

See Also clustered index, Fast Index Creation, index.

**segment**
A division within an InnoDB tablespace. If a tablespace is analogous to a directory, the segments are analogous to files within that directory. A segment can grow. New segments can be created.

For example, within a file-per-table tablespace, table data is in one segment and each associated index is in its own segment. The system tablespace contains many different segments, because it can hold many tables and their associated indexes. Prior to MySQL 8.0, the system tablespace also includes one or more rollback segments used for undo logs.

Segments grow and shrink as data is inserted and deleted. When a segment needs more room, it is extended by one extent (1 megabyte) at a time. Similarly, a segment releases one extent's worth of space when all the data in that extent is no longer needed.

See Also extent, file-per-table, rollback segment, system tablespace, tablespace, undo log.

**selectivity**
A property of data distribution, the number of distinct values in a column (its cardinality) divided by the number of records in the table. High selectivity means that the column values are relatively unique, and can retrieved efficiently through an index. If you (or the query optimizer) can predict that a test in a `WHERE` clause only matches a small number (or proportion) of rows in a table, the overall query tends to be efficient if it evaluates that test first, using an index.

See Also cardinality, query.

**semi-consistent read**
A type of read operation used for `UPDATE` statements, that is a combination of READ COMMITTED and consistent read. When an `UPDATE` statement examines a row that is already locked, InnoDB returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again, and this time InnoDB either locks it or waits for a lock on it. This type of read operation can only happen when the transaction has the READ COMMITTED isolation level.

See Also consistent read, isolation level, READ COMMITTED.

**SERIALIZABLE**
The isolation level that uses the most conservative locking strategy, to prevent any other transactions from inserting or changing data that was read by this transaction, until it is finished. This way, the same query can be run over and over within a transaction, and be certain to retrieve the same set of results each time. Any attempt to change data that was committed by another transaction since the start of the current transaction, cause the current transaction to wait.

This is the default isolation level specified by the SQL standard. In practice, this degree of strictness is rarely needed, so the default isolation level for InnoDB is the next most strict, REPEATABLE READ.

See Also ACID, consistent read, isolation level, locking, REPEATABLE READ, transaction.

**serialized dictionary information (SDI)**
Dictionary object metadata in serialized form. SDI is stored in JSON format.

As of MySQL 8.0.3, SDI is present in all InnoDB tablespace files except for temporary tablespace and undo tablespace files. The presence of SDI in tablespace files provides metadata redundancy. For example, dictionary object metadata can be extracted from tablespace files using the `ibd2sdi` utility if the data dictionary becomes unavailable.

For a MyISAM table, SDI is stored in a `.sdi` metadata file in the schema directory. An SDI metadata file is required to perform an `IMPORT TABLE` operation.
See Also file-per-table, general tablespace, system tablespace, tablespace.

server
A type of program that runs continuously, waiting to receive and act upon requests from another program (the client). Because often an entire computer is dedicated to running one or more server programs (such as a database server, a web server, an application server, or some combination of these), the term server can also refer to the computer that runs the server software.
See Also client, mysqld.

server-side prepared statement
A prepared statement managed by the MySQL server. Historically, issues with server-side prepared statements led Connector/J and Connector/PHP developers to sometimes use client-side prepared statements instead. With modern MySQL server versions, server-side prepared statements are recommended for performance, scalability, and memory efficiency.
See Also client-side prepared statement, Connector/J, Connector/PHP, prepared statement.

service principal name
The name for a Kerberos named entity that represents a service.
See Also principal.

service ticket
A Kerberos ticket that provides access to an application service, such as the service provided by a web or database server.

servlet
See Also Connector/J.

session temporary tablespace
A temporary tablespace that stores user-created temporary tables and internal temporary tables created by the optimizer when InnoDB is configured as the on-disk storage engine for internal temporary tables.
See Also optimizer, temporary table, temporary tablespace.

shared lock
A kind of lock that allows other transactions to read the locked object, and to also acquire other shared locks on it, but not to write to it. The opposite of exclusive lock.
See Also exclusive lock, lock, transaction.

shared tablespace
Another way of referring to the system tablespace or a general tablespace. General tablespaces were introduced in MySQL 5.7. More than one table can reside in a shared tablespace. Only a single table can reside in a file-per-table tablespace.
See Also general tablespace, system tablespace.

sharp checkpoint
The process of flushing to disk all dirty buffer pool pages whose redo entries are contained in certain portion of the redo log. Occurs before InnoDB reuses a portion of a log file; the log files are used in a circular fashion. Typically occurs with write-intensive workloads.
See Also dirty page, flush, redo log, workload.

shutdown
The process of stopping the MySQL server. By default, this process cleans up operations for InnoDB tables, so InnoDB can be slow to shut down, but fast to start up later. If you skip the cleanup operations, it is fast to shut down but the cleanup must be performed during the next restart.
The shutdown mode for InnoDB is controlled by the innodb_fast_shutdown option.
See Also fast shutdown, InnoDB, slow shutdown, startup.

slave
See replica.

slow query log
A type of log used for performance tuning of SQL statements processed by the MySQL server. The log information is stored in a file. You must enable this feature to use it. You control which categories of “slow” SQL statements are logged. For more information, see Section 7.4.5, “The Slow Query Log”.
See Also general query log, log.

slow shutdown
A type of shutdown that does additional InnoDB flushing operations before completing. Also known as a clean shutdown. Specified by the configuration parameter innodb_fast_shutdown=0 or the command SET GLOBAL innodb_fast_shutdown=0; . Although the shutdown itself can take longer, that time should be saved on the subsequent startup.
See Also clean shutdown, fast shutdown, shutdown.

snapshot
A representation of data at a particular time, which remains the same even as changes are committed by other transactions. Used by certain isolation levels to allow consistent reads.
See Also commit, consistent read, isolation level, transaction.

sort buffer
The buffer used for sorting data during creation of an InnoDB index. Sort buffer size is configured using the innodb_sort_buffer_size configuration option.

source
A database server machine in a replication scenario that processes the initial insert, update, and delete requests for data. These changes are propagated to, and repeated on, other servers known as replicas.
See Also replica, replication.

space ID
An identifier used to uniquely identify an InnoDB tablespace within a MySQL instance. The space ID for the system tablespace is always zero; this same ID applies to all tables within the system tablespace or within a general tablespace. Each file-per-table tablespace and general tablespace has its own space ID.

Prior to MySQL 5.6, this hardcoded value presented difficulties in moving InnoDB tablespace files between MySQL instances. Starting in MySQL 5.6, you can copy tablespace files between instances by using the transportable tablespace feature involving the statements FLUSH TABLES ... FOR EXPORT, ALTER TABLE ... DISCARD TABLESPACE, and ALTER TABLE ... IMPORT TABLESPACE. The information needed to adjust the space ID is conveyed in the .cfg file which you copy along with the tablespace. See Section 17.6.1.3, “Importing InnoDB Tables” for details.
See Also .cfg file, file-per-table, general tablespace, .ibd file, system tablespace, tablespace, transportable tablespace.

sparse file
A type of file that uses file system space more efficiently by writing metadata representing empty blocks to disk instead of writing the actual empty space. The InnoDB transparent page compression feature relies on sparse file support. For more information, see Section 17.9.2, “InnoDB Page Compression”.
See Also hole punching, transparent page compression.

spin
A type of wait operation that continuously tests whether a resource becomes available. This technique is used for resources that are typically held only for brief periods, where it is more efficient to wait in a “busy loop” than
to put the thread to sleep and perform a context switch. If the resource does not become available within a short
time, the spin loop ceases and another wait technique is used.
See Also latch, lock, mutex, wait.

SPN
See service principal name.

Spring
A Java-based application framework designed for assisting in application design by providing a way to configure
components.
See Also J2EE.

SQL
The Structured Query Language that is standard for performing database operations. Often divided into the
categories DDL, DML, and queries. MySQL includes some additional statement categories such as replication.
See Chapter 11, Language Structure for the building blocks of SQL syntax, Chapter 13, Data Types for the data
types to use for MySQL table columns, Chapter 15, SQL Statements for details about SQL statements and their
associated categories, and Chapter 14, Functions and Operators for standard and MySQL-specific functions to
use in queries.
See Also DDL, DML, query, replication.

SQLState
An error code defined by the JDBC standard, for exception handling by applications using Connector/J.
See Also Connector/J, JDBC.

SSD
Acronym for “solid-state drive”. A type of storage device with different performance characteristics than a
traditional hard disk drive (HDD): smaller storage capacity, faster for random reads, no moving parts, and with
a number of considerations affecting write performance. Its performance characteristics can influence the
throughput of a disk-bound workload.
See Also disk-bound, HDD.

SSL
Acronym for “secure sockets layer”. Provides the encryption layer for network communication between an
application and a MySQL database server.
See Also keystore, truststore.

ST
See service ticket.

startup
The process of starting the MySQL server. Typically done by one of the programs listed in Section 6.3, “Server
and Server-Startup Programs”. The opposite of shutdown.
See Also shutdown.

statement interceptor
A type of interceptor for tracing, debugging, or augmenting SQL statements issued by a database application.
Sometimes also known as a command interceptor.

In Java applications using Connector/J, setting up this type of interceptor involves implementing the
com.mysql.jdbc.StatementInterceptorV2 interface, and adding a statementInterceptors property
to the connection string.

In Visual Studio applications using Connector/NET, setting up this type of interceptor involves defining a class
that inherits from the BaseCommandInterceptor class and specifying that class name as part of the connection string.
See Also command interceptor, connection string, Connector/J, Connector/NET, interceptor, Java, Visual Studio.

statement-based replication
A form of replication where SQL statements are sent from the source and replayed on the replica. It requires some care with the setting for the `innodb_autoinc_lock_mode` option, to avoid potential timing problems with auto-increment locking.
See Also auto-increment locking, innodb_autoinc_lock_mode, replica, replication, row-based replication, source.

statistics
Estimated values relating to each InnoDB table and index, used to construct an efficient query execution plan. The main values are the cardinality (number of distinct values) and the total number of table rows or index entries. The statistics for the table represent the data in its primary key index. The statistics for a secondary index represent the rows covered by that index.

The values are estimated rather than counted precisely because at any moment, different transactions can be inserting and deleting rows from the same table. To keep the values from being recalculated frequently, you can enable persistent statistics, where the values are stored in InnoDB system tables, and refreshed only when you issue an ANALYZE TABLE statement.

You can control how NULL values are treated when calculating statistics through the `innodb_stats_method` configuration option.

Other types of statistics are available for database objects and database activity through the INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables.
See Also cardinality, index, INFORMATION_SCHEMA, NULL, Performance Schema, persistent statistics, primary key, query execution plan, secondary index, table, transaction.

stemming
The ability to search for different variations of a word based on a common root word, such as singular and plural, or past, present, and future verb tense. This feature is currently supported in MyISAM full-text search feature but not in FULLTEXT indexes for InnoDB tables.
See Also full-text search, FULLTEXT index.

stopword
In a FULLTEXT index, a word that is considered common or trivial enough that it is omitted from the search index and ignored in search queries. Different configuration settings control stopword processing for InnoDB and MyISAM tables. See Section 14.9.4, “Full-Text Stopwords” for details.
See Also FULLTEXT index, search index.

storage engine
A component of the MySQL database that performs the low-level work of storing, updating, and querying data. In MySQL 5.5 and higher, InnoDB is the default storage engine for new tables, superceding MyISAM. Different storage engines are designed with different tradeoffs between factors such as memory usage versus disk usage, read speed versus write speed, and speed versus robustness. Each storage engine manages specific tables, so we refer to InnoDB tables, MyISAM tables, and so on.

The MySQL Enterprise Backup product is optimized for backing up InnoDB tables. It can also back up tables handled by MyISAM and other storage engines.
See Also InnoDB, MySQL Enterprise Backup, table type.

stored generated column
A column whose values are computed from an expression included in the column definition. Column values are evaluated and stored when rows are inserted or updated. A stored generated column requires storage space and can be indexed.

Contrast with virtual generated column.
See Also base column, generated column, virtual generated column.

stored object
A stored program or view.

stored program
A stored routine (procedure or function), trigger, or Event Scheduler event.

stored routine
A stored procedure or function.

strict mode
The general name for the setting controlled by the innodb_strict_mode option. Turning on this setting causes certain conditions that are normally treated as warnings, to be considered errors. For example, certain invalid combinations of options related to file format and row format, that normally produce a warning and continue with default values, now cause the CREATE TABLE operation to fail. innodb_strict_mode is enabled by default in MySQL 5.7.

MySQL also has something called strict mode. See Section 7.1.11, “Server SQL Modes”. See Also file format, innodb_strict_mode, row format.

sublist
Within the list structure that represents the buffer pool, pages that are relatively old and relatively new are represented by different portions of the list. A set of parameters control the size of these portions and the dividing point between the new and old pages. See Also buffer pool, eviction, list, LRU.

supremum record
A pseudo-record in an index, representing the gap above the largest value in that index. If a transaction has a statement such as SELECT ... FROM ... WHERE col > 10 FOR UPDATE;, and the largest value in the column is 20, it is a lock on the supremum record that prevents other transactions from inserting even larger values such as 50, 100, and so on. See Also gap, infimum record, pseudo-record.

surrogate key
Synonym name for synthetic key. See Also synthetic key.

synthetic key
An indexed column, typically a primary key, where the values are assigned arbitrarily. Often done using an auto-increment column. By treating the value as completely arbitrary, you can avoid overly restrictive rules and faulty application assumptions. For example, a numeric sequence representing employee numbers might have a gap if an employee was approved for hiring but never actually joined. Or employee number 100 might have a later hiring date than employee number 500, if they left the company and later rejoined. Numeric values also produce shorter values of predictable length. For example, storing numeric codes meaning “Road”, “Boulevard”, “Expressway”, and so on is more space-efficient than repeating those strings over and over.

Also known as a surrogate key. Contrast with natural key. See Also auto-increment, natural key, primary key, surrogate key.

system tablespace
One or more data files (ibdata files) containing the metadata for InnoDB-related objects, and the storage areas for the change buffer, and the doublewrite buffer. It may also contain table and index data for InnoDB tables if tables were created in the system tablespace instead of file-per-table or general tablespaces. The data and metadata in the system tablespace apply to all databases in a MySQL instance.
Prior to MySQL 5.6.7, the default was to keep all InnoDB tables and indexes inside the system tablespace, often causing this file to become very large. Because the system tablespace never shrinks, storage problems could arise if large amounts of temporary data were loaded and then deleted. In MySQL 8.0, the default is file-per-table mode, where each table and its associated indexes are stored in a separate .ibd file. This default makes it easier to use InnoDB features that rely on DYNAMIC and COMPRESSED row formats, such as table compression, efficient storage of off-page columns, and large index key prefixes.

Keeping all table data in the system tablespace or in separate .ibd files has implications for storage management in general. The MySQL Enterprise Backup product might back up a small set of large files, or many smaller files. On systems with thousands of tables, the file system operations to process thousands of .ibd files can cause bottlenecks.

InnoDB introduced general tablespaces in MySQL 5.7.6, which are also represented by .ibd files. General tablespaces are shared tablespaces created using CREATE TABLESPACE syntax. They can be created outside of the data directory, are capable of holding multiple tables, and support tables of all row formats. See Also change buffer, compression, data dictionary, database, doublewrite buffer, dynamic row format, file-per-table, general tablespace, .ibd file, ibdata file, innodb_file_per_table, instance, MySQL Enterprise Backup, off-page column, tablespace, undo log.

Table
Each MySQL table is associated with a particular storage engine. InnoDB tables have particular physical and logical characteristics that affect performance, scalability, backup, administration, and application development.

In terms of file storage, an InnoDB table belongs to one of the following tablespace types:

- The shared InnoDB system tablespace, which is comprised of one or more ibdata files.
- A file-per-table tablespace, comprised of an individual .ibd file.
- A shared general tablespace, comprised of an individual .ibd file. General tablespaces were introduced in MySQL 5.7.6.

.ibd data files contain both table and index data.

InnoDB tables created in file-per-table tablespaces can use DYNAMIC or COMPRESSED row format. These row formats enable InnoDB features such as compression, efficient storage of off-page columns, and large index key prefixes. General tablespaces support all row formats.

The system tablespace supports tables that use REDUNDANT, COMPACT, and DYNAMIC row formats. System tablespace support for the DYNAMIC row format was added in MySQL 5.7.6.

The rows of an InnoDB table are organized into an index structure known as the clustered index, with entries sorted based on the primary key columns of the table. Data access is optimized for queries that filter and sort on the primary key columns, and each index contains a copy of the associated primary key columns for each entry. Modifying values for any of the primary key columns is an expensive operation. Thus an important aspect of InnoDB table design is choosing a primary key with columns that are used in the most important queries, and keeping the primary key short, with rarely changing values.

See Also backup, clustered index, compact row format, compressed row format, compression, dynamic row format, Fast Index Creation, file-per-table, .ibd file, index, off-page column, primary key, redundant row format, row, system tablespace, tablespace.

table lock
A lock that prevents any other transaction from accessing a table. InnoDB makes considerable effort to make such locks unnecessary, by using techniques such as online DDL, row locks and consistent reads for...
processing DML statements and queries. You can create such a lock through SQL using the \texttt{LOCK TABLE} statement; one of the steps in migrating from other database systems or MySQL storage engines is to remove such statements wherever practical.

See Also consistent read, DML, lock, locking, online DDL, query, row lock, table, transaction.

table scan
See full table scan.

table statistics
See statistics.

table type
Obsolete synonym for storage engine. We refer to InnoDB tables, MyISAM tables, and so on.
See Also InnoDB, storage engine.

tablespace
A data file that can hold data for one or more InnoDB tables and associated indexes.

The \texttt{system} tablespace contains the InnoDB data dictionary, and prior to MySQL 5.6 holds all other InnoDB tables by default.

The \texttt{innodb_file_per_table} option, enabled by default in MySQL 5.6 and higher, allows tables to be created in their own tablespaces. File-per-table tablespaces support features such as efficient storage of off-page columns, table compression, and transportable table spaces. See Section 17.6.3.2, “File-Per-Table Tablespaces” for details.

InnoDB introduced general table spaces in MySQL 5.7.6. General table spaces are shared table spaces created using \texttt{CREATE TABLESPACE} syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats.

MySQL NDB Cluster also groups its tables into table spaces. See Section 25.6.11.1, “NDB Cluster Disk Data Objects” for details.

See Also compressed row format, data dictionary, data files, file-per-table, general table space, index, innodb_file_per_table, system table space, table.

Tcl
A programming language originating in the Unix scripting world. Sometimes extended by code written in C, C++, or Java. For the open-source Tcl API for MySQL, see Section 31.12, “MySQL Tcl API”.
See Also API.

temporary table
A table whose data does not need to be truly permanent. For example, temporary tables might be used as storage areas for intermediate results in complicated calculations or transformations; this intermediate data would not need to be recovered after a crash. Database products can take various shortcuts to improve the performance of operations on temporary tables, by being less scrupulous about writing data to disk and other measures to protect the data across restarts.

Sometimes, the data itself is removed automatically at a set time, such as when the transaction ends or when the session ends. With some database products, the table itself is removed automatically too.
See Also table.

temporary table space
InnoDB uses two types of temporary table space. Session temporary table spaces store user-created temporary tables and internal temporary tables created by the optimizer. The global temporary table space stores rollback segments for changes made to user-created temporary tables.
text collection
   The set of columns included in a **FULLTEXT index**.
   See Also **FULLTEXT index**.

TGS
   A Kerberos ticket-granting server. TGS can also refer to the ticket-granting service provided by a ticket-granting server.
   See Also **ticket-granting server**.

TGT
   See **ticket-granting ticket**.

thread
   A unit of processing that is typically more lightweight than a **process**, allowing for greater **concurrency**.
   See Also **concurrency**, **master thread**, **process**, **Pthreads**.

ticket-granting server
   In Kerberos, a server that provides tickets. The ticket-granting server (TGS) combined with an authentication server (AS) make up a key distribution center (KDC).

   TGS can also refer to the ticket-granting service provided by the ticket-granting server.
   See Also **authentication server**, **key distribution center**.

ticket-granting ticket
   In Kerberos, a ticket-granting ticket is presented to the ticket-granting server (TGS) to obtain service tickets for service access.
   See Also **ticket-granting server**.

Tomcat
   An open source **J2EE** application server, implementing the Java Servlet and JavaServer Pages programming technologies. Consists of a web server and Java servlet container. With MySQL, typically used in conjunction with **Connector/J**.
   See Also **J2EE**.

torn page
   An error condition that can occur due to a combination of I/O device configuration and hardware failure. If data is written out in chunks smaller than the **InnoDB page size** (by default, 16KB), a hardware failure while writing could result in only part of a page being stored to disk. The **InnoDB doublewrite buffer** guards against this possibility.
   See Also **doublewrite buffer**.

TPS
   Acronym for "**transactions** per second", a unit of measurement sometimes used in benchmarks. Its value depends on the **workload** represented by a particular benchmark test, combined with factors that you control such as the hardware capacity and database configuration.
   See Also **transaction**, **workload**.

transaction
   Transactions are atomic units of work that can be **committed** or **rolled back**. When a transaction makes multiple changes to the database, either all the changes succeed when the transaction is committed, or all the changes are undone when the transaction is rolled back.

   Database transactions, as implemented by **InnoDB**, have properties that are collectively known by the acronym **ACID**, for atomicity, consistency, isolation, and durability.
   See Also **ACID**, **commit**, **isolation level**, **lock**, **rollback**.
transaction ID
An internal field associated with each row. This field is physically changed by \texttt{INSERT}, \texttt{UPDATE}, and \texttt{DELETE} operations to record which transaction has locked the row.
See Also \texttt{implicit row lock}, \texttt{row}, \texttt{transaction}.

transparent page compression
A feature added in MySQL 5.7.8 that permits page-level compression for InnoDB tables that reside in file-per-table tablespaces. Page compression is enabled by specifying the \texttt{COMPRESSION} attribute with \texttt{CREATE} TABLE or \texttt{ALTER TABLE}. For more information, see Section 17.9.2, “InnoDB Page Compression”.
See Also file-per-table, hole punching, sparse file.

transportable tablespace
A feature that allows a \texttt{tablespace} to be moved from one instance to another. Traditionally, this has not been possible for InnoDB tablespaces because all table data was part of the system tablespace. In MySQL 5.6 and higher, the \texttt{FLUSH TABLES ... FOR EXPORT} syntax prepares an InnoDB table for copying to another server; running \texttt{ALTER TABLE ... DISCARD TABLESPACE} and \texttt{ALTER TABLE ... IMPORT TABLESPACE} on the other server brings the copied data file into the other instance. A separate \texttt{.cfg file}, copied along with the \texttt{.ibd file}, is used to update the table metadata (for example the \texttt{space ID}) as the tablespace is imported. See Section 17.6.1.3, “Importing InnoDB Tables” for usage information.
See Also \texttt{.cfg file}, \texttt{.ibd file}, \texttt{space ID}, \texttt{system tablespace}, \texttt{tablespace}.

troubleshooting
The process of determining the source of a problem. Some of the resources for troubleshooting MySQL problems include:

- Section 2.9.2.1, “Troubleshooting Problems Starting the MySQL Server”
- Section 8.2.22, “Troubleshooting Problems Connecting to MySQL”
- Section B.3.3.2, “How to Reset the Root Password”
- Section B.3.2, “Common Errors When Using MySQL Programs”
- Section 17.20, “InnoDB Troubleshooting”.

truncate
A DDL operation that removes the entire contents of a table, while leaving the table and related indexes intact. Contrast with \texttt{drop}. Although conceptually it has the same result as a \texttt{DELETE} statement with no \texttt{WHERE} clause, it operates differently behind the scenes: InnoDB creates a new empty table, drops the old table, then renames the new table to take the place of the old one. Because this is a DDL operation, it cannot be rolled back.

If the table being truncated contains foreign keys that reference another table, the truncation operation uses a slower method of operation, deleting one row at a time so that corresponding rows in the referenced table can be deleted as needed by any \texttt{ON DELETE CASCADE} clause. (MySQL 5.5 and higher do not allow this slower form of truncate, and return an error instead if foreign keys are involved. In this case, use a \texttt{DELETE} statement instead.
See Also DDL, \texttt{drop}, foreign key, rollback.

truststore
See Also SSL.

tuple
A technical term designating an ordered set of elements. It is an abstract notion, used in formal discussions of database theory. In the database field, tuples are usually represented by the columns of a table row. They could also be represented by the result sets of queries, for example, queries that retrieved only some columns of a table, or columns from joined tables.
See Also cursor.

two-phase commit

An operation that is part of a distributed transaction, under the XA specification. (Sometimes abbreviated as 2PC.) When multiple databases participate in the transaction, either all databases commit the changes, or all databases rollback the changes.

See Also commit, rollback, transaction, XA.

U

undo

Data that is maintained throughout the life of a transaction, recording all changes so that they can be undone in case of a rollback operation. It is stored in undo logs either within the system tablespace (in MySQL 5.7 or earlier) or in separate undo tablespaces. As of MySQL 8.0, undo logs reside in undo tablespaces by default.

See Also rollback, rollback segment, system tablespace, transaction, undo log, undo tablespace.

undo buffer

See undo log.

undo log

A storage area that holds copies of data modified by active transactions. If another transaction needs to see the original data (as part of a consistent read operation), the unmodified data is retrieved from this storage area.

In MySQL 5.6 and MySQL 5.7, you can use the innodb_undo_tablespaces variable have undo logs reside in undo tablespaces, which can be placed on another storage device such as an SSD. In MySQL 8.0, undo logs reside in two default undo tablespaces that are created when MySQL is initialized, and additional undo tablespaces can be created using CREATE UNDO TABLESPACE syntax.

The undo log is split into separate portions, the insert undo buffer and the update undo buffer.

See Also consistent read, rollback segment, SSD, system tablespace, transaction, undo tablespace.

undo log segment

A collection of undo logs. Undo log segments exists within rollback segments. An undo log segment might contain undo logs from multiple transactions. An undo log segment can only be used by one transaction at a time but can be reused after it is released at transaction commit or rollback. May also be referred to as an “undo segment”.

See Also commit, rollback, rollback segment, undo log.

undo tablespace

An undo tablespace contains undo logs. Undo logs exist within undo log segments, which are contained within rollback segments. Rollback segments have traditionally resided in the system tablespace. As of MySQL 5.6, rollback segments can reside in undo tablespaces. In MySQL 5.6 and MySQL 5.7, the number of undo tablespaces is controlled by the innodb_undo_tablespaces configuration option. In MySQL 8.0, two default undo tablespaces are created when the MySQL instance is initialized, and additional undo tablespaces can be created using CREATE UNDO TABLESPACE syntax.

For more information, see Section 17.6.3.4, “Undo Tablespaces”.

See Also rollback segment, system tablespace, undo log, undo log segment.

Unicode

A system for supporting national characters, character sets, code pages, and other internationalization aspects in a flexible and standardized way.

Unicode support is an important aspect of the ODBC standard. Connector/ODBC 5.1 is a Unicode driver, as opposed to Connector/ODBC 3.51, which is an ANSI driver.
See Also ANSI, Connector/ODBC, ODBC.

unique constraint
A kind of constraint that asserts that a column cannot contain any duplicate values. In terms of relational algebra, it is used to specify 1-to-1 relationships. For efficiency in checking whether a value can be inserted (that is, the value does not already exist in the column), a unique constraint is supported by an underlying unique index.
See Also constraint, relational, unique index.

unique index
An index on a column or set of columns that have a unique constraint. Because the index is known not to contain any duplicate values, certain kinds of lookups and count operations are more efficient than in the normal kind of index. Most of the lookups against this type of index are simply to determine if a certain value exists or not. The number of values in the index is the same as the number of rows in the table, or at least the number of rows with non-null values for the associated columns.

Change buffering optimization does not apply to unique indexes. As a workaround, you can temporarily set unique_checks=0 while doing a bulk data load into an InnoDB table.
See Also cardinality, change buffering, unique constraint, unique key.

unique key
The set of columns (one or more) comprising a unique index. When you can define a WHERE condition that matches exactly one row, and the query can use an associated unique index, the lookup and error handling can be performed very efficiently.
See Also cardinality, unique constraint, unique index.

UPN
See user principal name.

user principal name
The name for a Kerberos named entity that represents a user.
See Also principal.

V

variable-length type
A data type of variable length. VARCHAR, VARBINARY, and BLOB and TEXT types are variable-length types.

InnoDB treats fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.
See Also off-page column, overflow page.

victim
The transaction that is automatically chosen to be rolled back when a deadlock is detected. InnoDB rolls back the transaction that has updated the fewest rows.

Deadlock detection can be disabled using the innodb_deadlock_detect configuration option.
See Also deadlock, deadlock detection, innodb_lock_wait_timeout, transaction.

view
A stored query that when invoked produces a result set. A view acts as a virtual table.

virtual column
See virtual generated column.
virtual generated column
A column whose values are computed from an expression included in the column definition. Column values are not stored, but are evaluated when rows are read, immediately after any BEFORE triggers. A virtual generated column takes no storage. InnoDB supports secondary indexes on virtual generated columns.

Contrast with stored generated column.
See Also base column, generated column, stored generated column.

virtual index
A virtual index is a secondary index on one or more virtual generated columns or on a combination of virtual generated columns and regular columns or stored generated columns. For more information, see Section 15.1.20.9, “Secondary Indexes and Generated Columns”.
See Also secondary index, stored generated column, virtual generated column.

Visual Studio
For supported versions of Visual Studio, see the following references:

• Connector/NET: Connector/NET Versions
• Connector/C++ 8.0: Platform Support and Prerequisites

See Also Connector/C++, Connector/NET.

W

wait
When an operation, such as acquiring a lock, mutex, or latch, cannot be completed immediately, InnoDB pauses and tries again. The mechanism for pausing is elaborate enough that this operation has its own name, the wait. Individual threads are paused using a combination of internal InnoDB scheduling, operating system wait() calls, and short-duration spin loops.

On systems with heavy load and many transactions, you might use the output from the SHOW INNODB STATUS command or Performance Schema to determine whether threads are spending too much time waiting, and if so, how you can improve concurrency.
See Also concurrency, latch, lock, mutex, Performance Schema, spin.

warm backup
A backup taken while the database is running, but that restricts some database operations during the backup process. For example, tables might become read-only. For busy applications and websites, you might prefer a hot backup.
See Also backup, cold backup, hot backup.

warm up
To run a system under a typical workload for some time after startup, so that the buffer pool and other memory regions are filled as they would be under normal conditions. This process happens naturally over time when a MySQL server is restarted or subjected to a new workload.

Typically, you run a workload for some time to warm up the buffer pool before running performance tests, to ensure consistent results across multiple runs; otherwise, performance might be artificially low during the first run.

In MySQL 5.6, you can speed up the warmup process by enabling the innodb_buffer_pool_dump_at_shutdown and innodb_buffer_pool_load_at_startup configuration options, to bring the contents of the buffer pool back into memory after a restart. These options are enabled by default in MySQL 5.7. See Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”.
See Also buffer pool, workload.
workload
    The combination and volume of SQL and other database operations, performed by a database application
during typical or peak usage. You can subject the database to a particular workload during performance testing to
identify bottlenecks, or during capacity planning.
See Also bottleneck, CPU-bound, disk-bound, SQL.

write combining
    An optimization technique that reduces write operations when dirty pages are flushed from the InnoDB buffer
pool. If a row in a page is updated multiple times, or multiple rows on the same page are updated, all of those
changes are stored to the data files in a single write operation rather than one write for each change.
See Also buffer pool, dirty page, flush.

XA
    A standard interface for coordinating distributed transactions, allowing multiple databases to participate in a
transaction while maintaining ACID compliance. For full details, see Section 15.3.8, “XA Transactions”.
    XA Distributed Transaction support is enabled by default.
See Also ACID, binary log, commit, transaction, two-phase commit.

Y
    young
    A characteristic of a page in the InnoDB buffer pool meaning that it has been accessed recently, and so is
moved within the buffer pool data structure, so that it is not flushed too soon by the LRU algorithm. This term is
used in some INFORMATION_SCHEMA column names of tables related to the buffer pool.
See Also buffer pool, flush, INFORMATION_SCHEMA, LRU, page.
